Mr. Lewis allows that calculations on both amortization and depreciation are largely tentative and may require subsequent modification. It appears to me that he should carry the logical deductions further than he does. Obviously, for a mine to be profitable it must return the capital invested plus a suitable rate of interest during its life. This, however, in no way infers that the amount of capital should be treated in any specified manner. Nor can I see that amortization or a sinking fund is necessary for this fact to be generally understood.

That depreciation should be allowed for in calculating cost appears to me to be axiomatic. This is mainly because the wearing out of plant has a direct bearing on the future cost. If we suppose a mine in the working of which it was known that no replacement of plant would take place and no appreciable increase in cost of maintenance and repairs, then depreciation would not necessarily be a part of sound business. No such cases, of course, occur. Therefore depreciation should form a sinking fund against replacement and against future increase of maintenance and repairs as the plant wears out. Once the fund reaches dimensions sufficient to cover these requirements, it should cease to be further increased. To continue adding to the fund until at the finish of the mine it equals the full cost of the plant is simply equivalent to amortizing that portion of the capital which has been spent in plant. If any company elects to do this, there is nothing to be said about it. I claim merely that such a proceeding is not necessary to good finance. What appears to me to be sound business is that depreciation of plant should be written off so that future replacements and increased cost of maintenance should be distributed as fairly as feasible over the whole period of working. Less than this would certainly result in the cost tending to increase as time went on. This means that the cost during the earlier years, being smaller than can be maintained, gives a wrong impression of the capabilities of the mine as to profit-paying. Toward the finish of the mine's life, when it was reasonably certain that no further replacements would be made, it would

be quite sound if those concerned preferred it, to distribute the fund accumulated for depreciation. Thereafter maintenance and repairs would keep the plant in condition.

Mr. Lewis says that "the replacing of several machines by one capable of doing the same work * * * , in short all expense necessary to keep the plant up-to-date and in proper operating condition, should be charged to depreciation, and not to capital." I think this requires amplifying. If such alterations mean installation that if effected at the beginning would have cost more than did the plant being altered or replaced, then the difference of cost is a fair charge to capital. It is the same as an extension of the plant, subsequently added to secure certain advantages in cost, tonnage, or extraction. The value of the replaced plant as it stands in the books (that is, its original cost less the amount written off in depreciation) less its selling-value is a correct charge to depreciation. Mr. Lewis in writing "all expenses, etc. * * *," probably means all expense over and above the usual work of "maintenance and repairs." The latter is an expense for the purpose of keeping the plant in proper operating condition. It could be included in depreciation. I think that few would consider this desirable. Certainly I do not. I consider that depreciation should not be used as a current working account but reserved for special work of replacement, including some of the bigger jobs of repairing.

Whatever may be the precise limits set to depreciation-accounts, it is generally agreed that it should be provided for. I submit, however, that the application of complicated formulas in arriving at allocations are inconsistent and liable to give the impression that the bases on which the allocations are calculated are certainties, which they are not.

Of the two forms of depreciation, physical and functional, the latter certainly depends upon an unknown factor, the future. Any provision made against it is mere guess-work based on general knowledge that from time to time new machines are invented or perfected that will replace existing ones. To apply formulas to allocations against such contingencies is entirely out of place. With regard to physical depreciation, we have something tangible to work on. We have experience with similar machines, and judgment can to some extent allow for the precise operating circumstances of particular machines. Even among the most favorable cases, however, it is rare that the factors are sufficiently certain to justify the use of complicated formulas.

In some industries, such as shipping and railways, the conditions may be sufficiently known. In long-established colliery districts and even in certain metal mines it may also be so. I submit that in the great bulk of metal mines it is not so. Changes and differences in metallurgical practice, changes and differences in character of ore (in depth or in different parts of the ore deposit), changes and differences in water, and even in climate, make formulas inapplicable.

Functional depreciation can be estimated only peri-

odically in the light of new factors which may have arisen since previous valuations. I submit that physical depreciation should be dealt with similarly, that is, it should be assessed periodically on the actual facts of the particular case and not by any formula or even rule-of-thumb. The points for consideration are, how long a life lies before it and what are the costs of maintenance going to be during that life. Such assessments made periodically will give the depreciation by differences. This can only be suitably done by those knowing the plant, or better even, by those actually using it. Of course, general experience as regards the average life of different machines is borne in mind.

In assessing functional depreciation, it is necessary to decide first on the manner of viewing it. If a machine has become obsolete, that is, if another machine has come into existence which would do work better and which would be installed in its place were the plant still to be erected, the logical issue would be: at what figure would it pay to continue using the existing machine as against a new one. That figure would be its value based on functional depreciation. Generally in such a case the value of the existing machine would be nil. There are cases where, while replacement would increase the profit, it would not increase it sufficiently to justify the cost of replacement. Frequently interruption to the work while the change was being made would form a heavier item for the replacement to repay than its own direct cost. In cases where, though a machine is obsolete, it would not pay to replace it, its value would be assessed merely at its selling-value (generally nil) or at its first cost less physical depreciation, according to the point of view. I would assess it on the latter basis, but would allow a larger depreciation than the purely physical one in view of its obsolescence, which has increased the probability of its being replaced in the future.

The application of functional depreciation in its entirety is open to difficulties. In cases where plant is replaced, the issue is clear. The replaced plant should be valued merely at its selling-value. Let us suppose, however, a whole treatment-plant that could be replaced by another, which would increase profits to such an extent that, while the change is not fully warranted, it would give additional profit rated at 75% of the book-value of the existing plant. Would it be advisable or correct therefore forthwith to write-down the plant by 75%? I think that most companies would decline to do so. Shortly, the application of functional depreciation in its entirety until such time as replacement is decided on, would be too full of complications and contentions to make its adoption desirable. Until actual replacement is decided upon, or at least foreseen, depreciation is suitably restricted to physical decay. An additional allowance in view of obsolescence may, or may not, be made according to the circumstances.

Mr. Lewis is quite correct in his contention that reliance can be placed on the law of averages as instanced by the mortality-tables of insurance companies. That closely accurate average lives of different machines could

be obtained, there is no doubt. What we want, however, in depreciation are the facts regarding a few machines and these, as he says, show a wide divergence from the average. He seems to me to come to the wrong deduction. The correct parallel would be whether, because averages can be reasonably relied on, a man would therefore be logical in assuming a certain life ahead of him or then, wishing to have accumulated a certain sum at date of his death, apply formulas to arrive at what sum he should periodically pay to a sinking fund for that object. This certainly would be unsound and would leave the very risks that insurance companies exist to eliminate. If insurance of plant against depreciation were feasible the law of averages would give the figures to work on. In calculating premiums in such cases formulas would be justified and necessary. It seems a pity that insurance against depreciation cannot be instituted. The premium it would place on careless use of plant would no doubt prohibit such being done. This applies to physical depreciation. Functional depreciation would be too open to disputes to permit of it.

In the above I have dealt with amortization and depreciation as applied to the creating of sinking funds, that is, to withholding of distribution of profits. From the point of view on the balance-sheets reflecting truly the actual value of assets, there is no doubt that at the end of a mine's life the plant should have been written-down to the selling-value of the plant at that date. This does not apply to amortization of capital. The value, at any date, of a mine does not depend on the capital invested. It depends upon the profit still to be won from the ore. The balance-sheet of a mining company does not give the actual value of all the assets. It does not do so with regard to the main thing—the ore deposit. However, it does purport to give the value of other assets, and I think it may be agreed that it should show the value of the plant at decreasing amounts, until, at the end of the mine's life, this shows only at its selling-value. Toward the end of a mine's life while depreciation was being written off the accounts, but not put into a sinking fund—not deducted from dividends—this would make it appear that that part of the distributed profit was payment out of capital. There seems no objection to this, as long as it does not masquerade as something else. Anyhow, the balance-sheet would show clearly that while certain profits are being paid the value of the assets is decreasing and any sensible person would recognize that to arrive at his true profit he must deduct his proportion of the decrease in value of assets. This comes back to a similar issue to that raised in connection with amortization of capital. If on the end being in sight and it being determined that no more replacements would be made, it were decided to distribute the amount lying in the depreciation sinking fund, this also would appear in the accounts as a payment from capital, similar to depreciation written off the assets but not deducted from dividends.

If it were considered unsuitable to thus make payments 'out of capital,' the case could be met by treating

the depreciation sinking fund as a suspense account.

In the above, amortization is discussed on its own merits alone. I agree, however, that the establishing of a sinking fund might serve, in the absence of other suitable or sufficient reserve, a most useful purpose. It would form a reserve that could be utilized, in case of need, to carry a mine over a critical period, such, for instance, as might be caused by a labor strike, by a sudden large increase in water, a caving or a fire in the mine, destruction of plant by fire, unforeseen difficulties with treatment or with plant. For this purpose, however, the fund would be useless in the early period of working, and it would become probably unnecessarily large in the later period. The use of the fund for such a purpose would be contrary to the idea of amortization. Still, it would be there as a real insurance, and could be diverted to such use if required.

I am of the opinion that a reserve should exist against such possibilities. There is, however, no consistency in forming such a reserve to start gradually with nothing and to accumulate by installments based on rule-of-thumb or on formula. It is often in the earliest period of working that such a reserve is needed. That period is not protected by the creating of a sinking fund. I submit that the consistent and business-like way of meeting the want is to provide for such a reserve in the initial capitalization. In some mines such reserve could be decreased after a period of working, when all the factors were better understood and conditions more settled. In others increased risks might appear and the amount be increased. In all cases the amount should be decided on the judgments of those best fitted to judge. In much of the older mining practice the function of such reserve was no doubt regarded as covered by the custom of calling up part of the capital only, leaving shares with liability for further payment. In modern practice this reserve seldom exists.

There are certain risks in mining that cannot be eliminated. There are others that can be. Among the latter is the risk of a mine being capable of paying satisfactory profits, but upset because of some unforeseen occurrence, which would not be fatal if a certain amount of money were available, but which without such may be fatal or very harmful. This is a risk that can be obviated in practically all cases, by the provision of a sum of money small in comparison with that spent on the actual development and equipment of the mine.

Amortization and depreciation, after all, are not matters vitally affecting the profitableness of a mine, whether they secure certain purposes of finance or not. A reserve such as described is a matter that may well affect the profitableness and even the very existence of a mine.

W. P. SLEEMAN.

Perth, Western Australia, February 17.

[This subject of Amortization and Depreciation goes to the base of mining economics. It is of universal interest and importance, and we shall be glad to have it discussed by others.—EDITOR.]

Misfires

The Editor:

Sir—May I add to this discussion of a subject far from unimportant, costing the mining industry a huge sum each year in lives, lost labor, and material. Misfires are always a serious problem to the miner in drift, stope, or shaft; he must find them, but not with a drill or pick first; later to bootleg them and lose part of a shift due to smoke and gas, or lose time mucking back when the lifters miss in the drift, or lose powder, shift, and all, because the cut-holes balked. Causes are easier to find than to apply the necessary remedies. The miner is often 'sot' in his ways, and when he bends his fuse sharply around a stick of powder, loading the primer muzzle-end first, there's a reason. He'd rather risk an occasional misfire than to risk withdrawing the fuse and cap with the tamping-stick, after putting the primer in correctly. He does not care to tamp in an upper where there is an exposed cap, and thus take advantage of the free use of the company's hospital. He can put the primer near the collar of the hole, but they might as well miss as to cut-off. I've been up against the trouble, and may say I'd rather search for missed holes that I had loaded than to hunt for the other fellow's misfires, and the following method will be found as good as any I have run across yet. A stick of powder has a wrapper folded at one end and crimped at the other. Take a 30-penny spike, or candlestick, and insert in the crimped end of the powder about three inches, making a hole in which the cap and fuse are inserted, then force in a small wooden plug, two inches long, alongside of the fuse and cap. This compresses the powder around the cap and fuse, so that it is difficult to withdraw the fuse. Next, if the primer is for an upper, split the cartridge in three places near the folded end, so that the cartridge can 'mushroom,' to keep it in place; there is then little chance of exposing a cap when the tamping-stick is withdrawn, while the cap is 'sighted' right and the fuse remains unbent. Try the plugs once and you are apt to keep plugging.

Mine Samples as Baggage

The Editor:

Sir—May I suggest to Mr. Stanton that the use of a good strong trunk will solve his problem. It can be taken as far as the hotel at the town where he leaves the railroad and the canvas sacks placed in it when he gets back to town before it is taken to the station. I have been following this practice for a good many years and have never had any trouble. I agree with him about the advantage to the railroad in the encouragement of examinations by responsible engineers. I have no doubt if the matter was properly brought to their attention permission could be had, but I have never known of anyone who has gone to that trouble. Sometimes it is preferable to keep the samples at hand in a little leather bag.

Boston, April 5.

ENGINEER.

THE CASA AT ALMADEN.

MAIN STREET IN ALMADEN.

Henry C. Perkins, and the Cost of Mining

AN INTERVIEW. By T. A. RICKARD

Mr. Perkins, where and when were you born?

On Staten island, New York, in 1846.

Where were you educated?

I attended schools in New York City, at Canaan, New Hampshire, at North Middleborough, Massachusetts, at Eagleswood, New Jersey, and finally I was a cadet at a military school on Staten island kept by M. Pujol, a Frenchman.

Did you have any special education for the mining profession?

I did not.

How did you chance to become connected with mining work?

When 17 years of age I was invited to accompany to California a cousin who had married Frederick Law Olmsted. Mr. Olmsted was general manager of the Mariposa Commercial & Mining Company, which was engaged in the development of the gold mines on the Mariposa Grant in Mariposa county. I was engaged in office work for the company when it ceased active mining in 1865.

What did you do then?

In October 1865 I entered the office of the New Almaden Quicksilver Mining Co. in San Francisco, where I served under the company's general manager, Samuel F. Butterworth, until 1870, first as assistant-accountant and then as accountant. At the same time I was secretary of a company that was mining borax and sulphur in Lake county. This company, by the way, I believe did the first mine dredging in California. The superintendent, C. W. Lightner, devised a bucket-dredge operated by hand-power. This was used to extract borax from Borax lake.

Where was your next work?

After a few months at New Almaden in charge of the office there, I went to North Bloomfield, in Nevada county, where as assistant to General A. M. Dobbie I became interested in testing the quality of the gravel in the ancient river-bed system. In 1871 Hamilton Smith was appointed manager of the North Bloomfield company and I became his assistant while he projected and started a bedrock tunnel to drain the deep channel. This tunnel was some 8000 ft. long in hard rock, and with the assistance of eight shafts the work was accomplished in less than three years by hand-work, excepting in the lower face where a diamond-drill was employed. The total cost of this tunnel was a little under \$500,000. At the same time larger storage-reservoirs were constructed in the mountains, some 40 miles distant and the canals connecting them with the mine were enlarged and improved.

Was Hamilton Smith a trained engineer?

Yes, he had trained himself by practical work in his father's coal mines in Indiana.

He was a man of great natural capacity for engineering work?

Yes. He was a masterful character, he had a powerful intellect, a great grasp of the controlling factors in any undertaking, and a genius for thoroughness. The most important incident in my career was my association with him, which lasted until his death in 1900.

What was Mr. Smith's later work?

In 1874 he turned over to me the superintendency of the North Bloomfield company and moved to San Francisco, where he was elected president of the company. While there he brought Baron Edmond de Rothschild to inspect the hydraulic mines at North Bloomfield. Through this introduction he became the consulting

engineer for the Rothschilds in Paris and London. For them he first inspected and reported upon the El Callao mine in Venezuela and subsequently advised them upon their mining affairs generally. Hamilton Smith was instrumental in introducing abroad the greater number of those American mining engineers who have brought so much credit to the profession. His figure bulks largest among the mining engineers I have known.

How long did you remain at North Bloomfield?

I remained in charge of the North Bloomfield company's properties and also those of the Milton company until 1883, when the attacks of the farmers, assisted by the Federal government, against the hydraulic miners, who were charged with destroying farming land and injuring the rivers and harbors, became so harrassing and expensive that I saw that hydraulic mining in California would be no longer profitable, and I therefore accepted an offer to go to Venezuela, and assume charge of a valuable gold-quartz mining property there for a term of three years.

How long did you remain in Venezuela?

I managed the El Callao mine for four years, that is from 1883 until 1887.

This was your first experience in mine management in a foreign country and with alien races?

Yes, and I found my experience valuable. I learned two things that have been of great assistance to me.

These were?

First: I learned that a foreigner in a strange country, irrespective of the character of the people and its degree of civilization should assume that the great principles of right and justice do not vary with different races, nor with different degrees of civilization. Those principles are universal and ever-lasting, and they should govern our actions always—not only where and when they seem advantageous. My observations have brought me to the conclusion that disasters that come to us abroad in dealing with the authorities have been nearly always the result of our departure from those first principles, whether the departure was owing to ignorance, accident, or design.

Second: I came to the conclusion, which has been confirmed by my later experience, that the differences in the intellectual, moral, and physical qualities of people are not racial, but are owing to local influences to which communities are subjected by education, opportunity, temptation, and particularly by the impress of masterful characters. I believe that there is not 25% difference in the intellectual, moral, and physical value of the various races of the world when they are submitted to the same influencing factors.

In mining work is it possible to bring to bear upon the uneducated and semi-civilized races the influence you refer to in a reasonably short time?

My experience indicates that the time required is surprisingly short and I have concluded that when planning a long campaign of work, if the locality has an

ample population, it is better to employ the local inhabitants in any kind of work, the simplest or most difficult, rather than to import labor from abroad. I make the proviso, however, that the effort must be made by those who are sympathetic with the race they employ, they must believe in the principle and they must have patience. These conclusions I have arrived at after a long experience in employing many races, white, black, and yellow for various kinds of work.

Probably not more than 10% of the individuals of any race is especially adapted by mental temperament and physical qualities to become very efficient in any particular task. Therefore to accumulate 100 of the most efficient workmen for any special employment, it will be necessary to select, by a process of elimination, this number out of 1000. For this reason an ample supply of men from which to choose is a highly important factor in securing the best results.

What is your opinion concerning the Chinese episode at Johannesburg?

I think it was a mistake; where an ample indigenous population is available it is better to train the natives for permanent work rather than to import foreign labor, although doing this may promise better immediate results. At the time the introduction of Chinese labor on the Rand was proposed I took this view, the reply was that an insufficient number of Kaffirs was available, a good reason if this had been a fact, which it was not as is now known.

Then you have come to the conclusion that in a long campaign of industrial effort it is best to employ the people of any populous neighborhood rather than to import labor from a distance whatever the race or prevailing state of civilization may be? If I am correctly informed, Mr. Perkins, you adopted the policy later when you were in Korea?

It would not be quite true to say that, because the policy was adopted by the men who preceded me. The policy had been forced by circumstances, but I accepted it and developed it sympathetically. When our company, the Oriental Consolidated, started working in Korea, the population in the neighborhood of the mine was almost exclusively agricultural, yet within three years the natives had learned to run the machinery, and were doing nearly all of the work of building mills, assaying ore, blacksmithing, as well as the underground mining. We have employed 5000 natives, with less than 60 white men, the latter chiefly in the accounting department, keeping tally of the stores, and handling and transporting the bullion. This number includes the manager and his staff. It suggests what can be done with an ignorant and entirely untrained people in a short time by making a sincere attempt to teach them how to be useful.

What was your experience in Venezuela?

In Venezuela we employed chiefly negroes from the West India islands, there being practically no local supply of labor. These negroes, whose only previous

THE NORTH BLOOMFIELD MINE.

training had been in agricultural work, for which they were paid about 25 cents per day, came to the mines and were paid \$3 per day. They soon became expert in nearly all kinds of mining labor, and, after some improvement in organization, with these men we produced and reduced the ore from the gold veins nearly as cheaply per ton as they did at that time at the Mysore mines, in India, where the laborers received only some 20 cents per day. The mining difficulties so far as width of lode and hardness of ore were concerned were practically the same. My mining experience in Mexico justi-

fies me in making the assertion that the mining cost there materially exceeds the cost in the United States, where the rate of wages is more than double.

Then you consider that the rate of wages is not an important factor in the cost of mining?

In certain cases it is an important factor, but I have come to the conclusion that usually its importance is much exaggerated. In estimating the value of a mining property I do not consider the rate of wages prevailing, however high or low it may be, as a vital consideration.

GELDENHUIS DEEP MINE, AT JOHANNESBURG.

As an illustration of the effect of the rate of wages upon the cost of mining I give the following table:

	Miners' wages	Cost per ton
Venezuela, in 1887	\$3.20	\$15.00
Mysore, in 1887	0.20	13.00
Alaska Treadwell	3.50 to 4.00	1.25
Mexico	0.50 to 0.75	4.50 to 5.50
California	3.00	2.50 to 3.00
Korea	0.25	2.50
Rand	0.75	4.00 to 5.00

In the Alaska Treadwell mine the great size of the deposit makes the conditions exceptional, otherwise I think the above comparison fairly indicates the singularly small effect that the rate of wages has upon mining costs. In India and on the Rand the unnecessarily large proportion of highly-paid foreign employees accounts materially for the high cost per ton in those localities.

Where did you go after leaving Venezuela?

I went to London and joined the firm of Smith & DeCrano. This firm had previously established the London Exploration company.

What work engaged your attention while a member of that firm?

I first examined gold mines in Mexico and later the Anaconda property in Montana. I then examined the Alaska Treadwell group of mines in Alaska and my firm purchased for the Exploration Company the control of these mines. I placed Capt. Thomas Mein, who had been my assistant in Venezuela, in charge of them.

After returning to London, Smith & DeCrano assumed the management of the London Exploration company and I established an office in that city for consulting work. I was appointed consulting engineer to the DeBeers Consolidated Mining Co., but this position was nominal, the direction of affairs being entirely in the hands of Gardner F. Williams.

How long did you remain in London?

For five years; until 1893 it continued to be my headquarters; in this period, however, I traveled extensively on mining examinations and undertook the development of a gold mine in Wales, which proved to be unprofitable.

Where else did you go?

In 1891 Lord Randolph Churchill decided to make a trip into Mashonaland, which in August of the previous year had been occupied by the British South Africa Company. Having been introduced to Lord Churchill by Lord Rothschild, I was invited to accompany the former as consulting engineer. Mashonaland was reported to contain valuable ore deposits.

How long did the trip take?

Some nine months, five of which were spent in Mashonaland and the remainder in traveling and observation in other mining districts.

What was your opinion of the mining prospects of Mashonaland?

I found gold widely distributed there and while at many places I saw rich ore, the veins and deposits were

generally too small and irregular to justify a foreign company in undertaking their development.

Did you also visit the Matabele country?

No; at that time it was controlled by the Matabeles, who did not permit white men to explore for mines.

Then your trip into Mashonaland as a mining venture was a failure?

Not entirely so, for on my way up the country I visited Johannesburg and became much interested in that district now famous as the Rand.

What were the conditions of the mining industry in the Transvaal at that time?

The basket gold deposits discovered some five years previously had had their first period of development with the inevitable share boom, which had collapsed, the first expectations not having been fulfilled. At that time several of the companies had paid dividends, but none except the Robinson, the ore of which then yielded \$40 per ton, had earned any actual profit, if the loss in scrapping inefficient plants were considered. In consequence the European investing public had largely lost its enthusiastic view of the value of these mines and the shares were much depressed in value.

You thought at that time that the profitable ore would persist into the untested ground on the dip of the conglomerate beds?

Yes. J. S. Curtis had previously advocated that view. It was obvious to anyone of mining experience. After looking over the situation I came to the conclusion that the district had a large intrinsic value, which would be demonstrated by improvements in methods, equipment, and management. I therefore took an active part in the development of the ground below the outcrop mines and after returning to London I interested large London and Paris financial houses in the mines of that district. In 1893, I was engaged by the firm of Wernher, Beit & Co. to manage the development of deep-level properties for a period of three years.

What sort of treatment did you get from the Boer government?

I thought that the government by the Boers was very good, considering the difficulties and temptations which the young nation was called upon to meet with so short a time for education in the new work suddenly imposed upon it. I saw no fair grounds for complaint except the oppressive dynamite monopoly and the difficulties thrown in the way of obtaining the franchise necessary to obtain any control over the taxes, which were almost entirely borne by the foreigners. This grievance, however, was rather academic than real, for the taxation was not excessive and few of the foreigners wished to become citizens, although naturally they chafed at the control over their persons and properties by an authority which many considered unfriendly.

The critical and hostile attitude of the foreigners toward the Boers and their government I thought was both irritating and unjust to them. This with the world-

SIFTING CINDERS AT A GOLD MINE IN INDIA.

wide unfortunate racial prejudice brought about that great tragedy, the Boer War.

You finished your term of three years on the Rand, and then?

I returned to Europe in 1896 and formed a partnership with Hamilton Smith. This association continued until his death in 1900.

What have you done since 1896?

I remained in Europe until 1898; in that year I returned to New York where Mr. Smith and I established an office where we cared for our various mining and other interests. In the following year I inspected mines in Korea, Siberia, Canada, and the United States, and in all of these regions I became interested in mining properties.

When you first went to Korea, in what condition were the mines?

A GROUP OF MEXICAN MINERS.

I went there with Leigh Hunt in 1900 and inspected the country 70 miles south-east of the Yalu river in north-western Korea. There was not much ore to be seen, and the gold was distributed in the quartz in a patchy way, making it difficult to estimate the available tonnage of ore. Mr. Hunt's company had done considerable development of the veins, extracting the rich ore wherever it was found. When I visited the property little good ore was in sight.

Did you sample the veins?

I did very little sampling. I mapped the work done by Mr. Hunt's company; an inspection of the maps showed that the ore had occurred in isolated spots and not in zones or shoots. After calculating that the yield of gold per square foot on the plane of the vein for the entire exploited ground had been \$4 per square foot over the reduction cost, I came to the conclusion that these veins could be worked profitably if they persisted in length and depth, and as there were no indications of their early giving out, I decided the venture was a good one. I have often employed this method of appraising the value of a mine that is being worked. In other words, the question to be decided usually is not what can be earned by the working of some tons of ore, but will the aggregate yield of gold be greater than the aggregate cost.

The experience of the Oriental Consolidated Mining Company in Korea has been interesting and instructive?

This company gained possession in 1897 of the mining rights on a concession in north-western Korea covering some 400 square miles of territory. Scattered indiscriminately over the area were many quartz veins carrying gold, in granite; the veins were generally small, the largest being rarely over 6 ft. in width. The ore was refractory, carrying a large proportion of the base metals.

The population in this locality was devoted usually to agricultural pursuits; what little quartz mining had been done had been performed by the primitive operation of gadding out seams of the richer ore, which was ground under rolling-stones and the residue panned to obtain the gold contents. The population had had no experience in the use of modern mining equipment. Local wages were 10 cents per day; the company paid the miners 25 cents per day at first; later this rate was somewhat increased. The communication facilities of the country were of the most primitive kind—the roads were almost impassable, the bridges were removed in the rainy season and were replaced each year.

In the past 19 years the company has erected six mills with 245 stamps, three cyanide works, hydro-electric plant including a dam 80 ft. high. It has established four general stores and a transportation service employing five vessels. It has mined and reduced 4,300,000 tons of ore, which yielded \$22,500,000, and it has paid in dividends to the shareholders \$7,500,000. To accomplish this it has used only some \$100,000 for development of the mines and the equipment of the property, every-

thing other than that sum has been paid out of profits. The company has employed from 3500 to 5000 natives and rarely more than 60 foreigners.

Considering the low grade of the ore treated and the necessity of breaking ground in a locality so isolated from all mining facilities and traditions the results certainly have been remarkable. In your opinion what were the chief factors in accomplishing these?

First, the lack of capital; this compelled the most rigid economy in the early days of the enterprise.

Second, the almost exclusive employment of native labor that was patiently trained to effective work by the small force of foreigners.

Have you any trouble now with the Japanese Government?

My experience with the Japanese has indicated to me that those of the official class controlling the Japanese Government affairs are broad-minded, clear-headed, and whatever their final motives be, and I do not question their good faith, I think they have too much sense to adopt a policy that is not just. My experience has been that while they have been exacting, to our cost and inconvenience, I cannot say that their action has been unreasonable or unjust, from their point of view.

They certainly have benefited the Korean people in all material matters by their excellent government—whether these benefits have compensated the Koreans for the suppression of their national spirit I am not sure.

I think that while the Japanese will not interfere with the operation of enterprises already in existence, they do not favor any new incursion of foreign capital into Korea, unless with very considerable and inconvenient restrictions.

You have then had over 50 years of mining experience.

Yes, and I have learned many things.

Will you mention some of the things you have learned?

I have already referred to the result of my experience in working in foreign countries and to my conclusions as to the influence of wage-rates upon mining costs.

The knowledge of mining costs you think a fundamental part of mining engineering?

Decidedly so. The first aim of the ore-seeker is to make a profit. If he fails in this he ceases to mine and the world loses the benefit of his production of the metals.

Has the science of metalliferous mining advanced during the fifty years of your experience?

Certainly.

What influences do you consider have chiefly brought about the improvements?

In my opinion over 90% of the progress is due to the following three agencies.

1. The work of the chemist and metallurgist. They have improved reduction methods, explosives, and the value of alloys.
2. The engineers, who have introduced labor-saving contrivances.

3. The general education of the managers of mines and their use of more scientific methods.

In what direction do you look for further advances in mining efficiency?

Doubtless the chemist, metallurgist, and engineer will be of further very material benefit, but probably the greatest advance will come from a better understanding of the proper relations between the employer and employee; in metalliferous mining usually the largest expense is labor, and by obtaining the best results from

business men I have known have been persistent investors in mines. In choosing their enterprises they have not been led away by the temptation offered by optimistic promoter's circulars, but were guided by sound consideration of the statement of men of character, ability, and experience.

Mining has its peculiar risks, but broadly speaking, no business enterprise is free from risk, although it may be of different character and come from different causes. The risk of mining, of course, is obvious to any man with

A FORCE OF KOREAN MINERS AT THE TARACOL MINE OF THE ORIENTAL CONSOLIDATED MINING CO.

labor most important benefits will follow.

What do you consider the best method that can be employed for increasing the efficiency of labor?

A sympathetic study by the employer of the point of view of the employee, and a system of profit-sharing that will tend to give the employee the point of view of the employer. The raising of wages cannot go on indefinitely without resulting in the closing-down of the poorer mines.

What is your opinion of mining as a business investment?

While mining has its venturesome side—made especially attractive by the almost limitless possibilities of profit—the general impression that all mining investments are peculiarly hazardous and speculative is, I think, wrong. In my experience some of the soundest

mining experience; it is obvious to us mining engineers, just as the risk of farming and real estate speculation is obvious to farmers and real-estate agents. That man is wise who deals in the things the risk of which he understands.

Therefore, Mr. Perkins, you will agree with me, I believe, that the mistake made by the public is not in considering metal mining a desirable form of using money, but the forgetting of the fact that it involves risk. Do you consider metal mining a legitimate form of investment?

Yes, I do, when the profit is sought from mining ore and not from kiting shares; in other words, by legitimate return on capital and not by the fictitious enhancement of the principal. 'Income' from mining investments is apt to be a misleading term if one forgets that the income

includes, in large measure, a return of capital, and many people who are accustomed to other kinds of investment overlook the necessary amortization of capital. Personally I charge the return from a mine to 'capital' until all the capital has been redeemed, and thenceforward I regard the return as profit. Moreover, I recognize that it is a profit that may cease at any time.

What is your opinion respecting the propriety of managers of mining companies—whose shares are on the market—dealing, excepting as investment, in the company's shares?

While there is nothing in itself dishonest in their doing this, I consider it a dangerous habit. When a man prays to be delivered from temptation he should not invite it.

You have known of many large fortunes accumulated through mining investments?

Yes.

Have these been made by share speculation or in a legitimate way?

I believe that almost without exception the large mining fortunes have been made by investment in mines that have yielded their owners a profit by the extraction of minerals from the ground, and that few, if any, of the large sums coming from purely stock speculations have resulted in permanent fortunes. Nor do I think mining promoters have been often successful in accumulating fortunes that have endured, excepting when they have dealt in mines of intrinsic value.

Do you favor publicity in the conduct of public companies?

I think that the shareholders in a public company are entitled to know everything as to its affairs that the management knows, and that hiding is not only indefensible but it is nearly always injurious to the best interests of the concern. Suppressing information deceives the unwary and aids the dishonestly disposed. Secrecy concerning the operations of a public company tends to create suspicion in the minds of the subordinates as to the good faith of those in control, it is likely to lower their moral standards and to discourage their enthusiastic co-operation. I am aware that the policy of secretiveness is often followed from good motives, but I believe it usually proves to be a mistaken policy.

To what, in your mining experience do you look back upon with the most satisfaction?

To the development of personalities and to the advancement of my subordinates from inferior positions to those of greater responsibility. I have been able to start a considerable number of young men on careers of great usefulness, and I have not felt that they were in debt to me for their successes, for the benefits arising from the association have been mutual.

What do you consider the chief factors you have employed in the development of these men?

The throwing upon them of responsibility and showing trust in them.

What qualities do you chiefly look for in selecting mining managers?

1. Strength of character.
2. An honest intellect which sees the facts as they are and not only as one may wish them to be.
3. A disposition to be just to the employee as well as to the employer.
4. A practical working experience.
5. A technical training.

While all of these qualities are rarely at first combined in any one individual they can be quickly developed in most individuals of fair character and intelligence.

Do you think mining is a good career for a young man?

Yes, for a good man who is likely to develop a love for the work. It seems to be that today there is less oversupply of mining engineers than of doctors and lawyers.

Have you any expectation of the expansion of mining as a world-wide industry?

There is an increasing demand for the metals and an increased supply of capital available for the exploitation of mines. Therefore, I expect an increase in mining activity the world over.

You were at Juneau last summer; how were you impressed by the new enterprises for the mining of low-grade ore?

I found the mining and reduction methods lately introduced at Juneau most interesting and instructive. If the companies operating there at the high rate of wages prevailing can demonstrate that hard ore can be extracted from underground workings and reduced profitably when the yield is only \$1 per ton, all hard-rock mining men will recognize that a new mark for efficient mining work has been established and the world will benefit by having its available wealth increased.

THE ACID RESISTING properties of some iron-silicon alloys was tested by O. L. Kavalke, taking 18 low-carbon iron-silicon alloys, containing 1.2 to 19.8% silicon, which were immersed from periods of 51 hr. to 29 days in 10% solutions of sulphuric, hydrochloric, nitric, acetic, and citric acids, and the losses determined. With a few irregularities the resistance to acid-attack was a minimum at 1.2 to 3.3% silicon, and a maximum at 16 to 18%. The latter alloys are hard and brittle. Attempts are being made to find an additional element which will decrease these undesirable qualities while not impairing the resistance to acids. The conclusions from the experiments were that (1) silicon-iron alloys of about 3 to 5% silicon are attacked readily by sulphuric, hydrochloric, acetic, and citric acids, and such alloys are not excessively brittle; (2) silicon-iron alloys of about 16 to 18% are exceedingly resistant to the action of sulphuric, hydrochloric, nitric, acetic, and citric acids, and the alloys are so brittle that they must be ground; they cannot be machined; and (3) a solid solution of FeSi in iron near 20% silicon is resistant to mineral acids.

SCHEELITE in large masses is reported to have been found recently in the southern part of New Zealand.

OUTCROP OF THE WHALE VEIN.

THE TELLURIDE CHIEF MINE.

Molybdenum in the Hualpai Mountains

By L. WEBSTER WICKES

The Hualpai mountains, pronounced and sometimes spelled Wallapai, are situated near the centre of Mohave county, Arizona, south and east of the main line of the Santa Fe railway, and rise from 2500 to 5000 ft. above the Big Sandy valley on the east and the Sacramento valley on the west. Hualpai peak attains an altitude of 8266 ft. above sea-level. The range extends north and south about 40 miles, with a maximum width of 15 miles.

The geology of the Hualpai range was described by W. T. Lee in Bulletin 352 of the U. S. Geological Survey and in Bulletin 397 by F. C. Schrader. Schrader says, "These mountains are composed of pre-Cambrian granitic rocks, and seem to be a fault-block tilted eastward." The slope is steep to the west, where there exists a wide belt of gneiss and several strong faults. Mining has been carried on intermittently here since 1871, when members of Lieut. Wheeler's exploring party found vein outcrops containing silver and gold. Silver was the object of search in the early days and resulted in the opening of a number of properties, mostly on the east slope. Later developments were on outcrops of copper and lead-zinc veins. During the last few years tungsten has excited interest. From some of the tungsten properties regular shipments of hand-sorted ore are being made. Bismuth and vanadium minerals are also found. Molybdenum has been known in these mountains for a long time. Traces of this metal are generally found wherever the surface has been eroded to the pre-Cambrian complex in Mohave county. It usually occurs as molybdenite, although occasionally wulfenite is found in the lead veins. It is most abundant just north of Wheeler wash, and near Deluge wash, both of which lead into the Big Sandy. Wheeler wash is near the north end of the range, and the properties are from 20 to 25 miles from Kingman. The Deluge area is 25 to 30 miles from Yucca, and was the first one in the district worked for molyb-

denum, where the Leviathan Mines Co. and the American Mineral & Chemical Co. are now operating. A description of the Leviathan is given by F. W. Horton in the Bureau of Mines Bulletin 111.

In the vicinity of the molybdenum deposits the country is a medium-grained granitic rock, which extends north and south for some distance, and must be very wide, but its east boundary is hidden by detrital material. It seems to be intrusive through coarse red granite and gneiss. Dark basic dikes are found to the south, west, and north, while several miles north-west rhyolite and latite are found. Near the deposits are small pegmatite stocks, which, however, seem to have no connection with the mineralization. The ore occurs in veins running nearly parallel with the main ridge and conformable to the principal jointure of the granite. It is a white quartz containing molybdenite and chalcopryrite, outcropping prominently. On the Whale vein, of the Leviathan company, the outcrop is strong for 1500 ft., with 'pinch and swell' from 18 in. to 30 ft. Underground it shows an average width of over 3 ft. There is a shaft 135 ft. deep, and about 700 ft. of driving and tunneling has been done. This vein is distinguished by crossing instead of conforming to the jointure of the granite. There is also more evidence of movement; the foot-wall being a clean slip, while the hanging wall is irregular. The metal-content is fairly uniform in vein-lets, stringers, and drusy material. I. C. Stricker, the manager, states that the ore gives an average of slightly under 2% MoS_2 , and a trifle over 2% copper. Bunches of high-grade are found repeatedly, and in one case a lens yielded 700 pounds of 67% ore. I estimate that over 16,000 tons of 2% ore is ready for stoping, and at least twice that amount of probable ore, while the possibilities are much greater. This relates only to the Whale vein, and there are others that give promise. A

50-ton mill has just been completed, and the first shipment of 30% MoS_2 concentrate is now being made. Concentration is entirely by flotation at present.

The Wheeler wash section presents a condition different from that at Deluge wash. The strong outcrops of quartz are entirely lacking, and no definite vein-system has been discovered. The country rock is similar, but lacks some of the accessory minerals. It has a finer grain and is sometimes porphyritic. It is interesting to note that though biotite is a constituent of the country rock, it seems to decrease in amount and is entirely lacking at places in close proximity to the ore deposits. This effect is sometimes noticeable for a distance of 10 feet.

In the granite at Wheeler wash are a number of north and south fractures showing a little movement. These show alteration and silicification, sericite and kaolin having also been developed. There are veinlets of secondary quartz, usually $\frac{1}{4}$ to $\frac{1}{2}$ in. wide, and occasionally as much as 4 inches. The fractures are nearly vertical, and are intersected at right angles by a system of minor vertical faults, with the throw nearly horizontal. These movements have produced coarsely brecciated zones in which the molybdenite is found. Where the alteration has been the greatest the percentage of molybdenite increases. Molybdenite is also found as thin flakes on the fault planes.

On the ground of the Telluride Chief Co. is a shaft 200 ft. deep with 350 ft. of work at the bottom. Roy Cornell, resident engineer of the company, informs me that a zone 30 ft. wide which has been cross-cut, assays 1% molybdenite. The total area where the molybdenum has been found is about one by two miles in both the Wheeler and Deluge wash districts. These areas are nearly 12 miles apart. The intervening country is being actively prospected.

Milling the ore is a serious problem. With the exception of some on the Arizona Molybdenite Co.'s ground, the ore contains pyrite and chalcopyrite. Buyers of molybdenite formerly insisted on having a product containing less than 1% copper and over 60% molybdenite. At the present time this condition does not have to be met, but will again in the future. The high percentage of chalcopyrite makes it difficult to obtain clean molybdenite. The American Co. has had an experimental mill in operation for some time; the Leviathan has just completed its new mill, with a capacity of 50 tons; and the Arizona Molybdenite Co. has a mill under construction. Considerable testing has been done with laboratory flotation-machines and good results obtained. It has proved difficult to bring the copper content below 5%. A good copper product is made in the laboratory, and it should be only a matter of further experimenting before it can be done in practice. Good results have been obtained by using a light oil, making an evanescent bubble, in a machine that can be skimmed quickly. Upon the addition of a heavy oil in a machine with long spitzkasten, the copper product is obtained. An ammonium resinate has been successfully used to float the molybdenite and leave the chalcopyrite behind. The best method has been to

make a concentrate in the first machine, floating all the sulphides, and then subjecting this concentrate to a light roast, after which the molybdenite can be readily floated leaving the copper and iron in the tailing.

The method of analysis which has been found most satisfactory, particularly when much copper is present, was developed by R. C. Jacobson of Mohave. It is as follows: Weigh 4 gm. in a casserole and add 10 cc. nitric acid; cover and heat to decomposition. After brown fumes have ceased, add 0.5 gm. potassium chlorate and heat until chlorine has ceased coming off. Add 3 cc. sulphuric acid, and evaporate to white fumes. Be sure that all the nitric acid has been expelled. Cool; dissolve in water and heat on the hot-plate until all has gone into solution; cool, and add an excess of ammonia (at least 5 or 6 cc. ammonia to 25 or 30 cc. water after the solution is neutralized). Heat to boiling for a few minutes, transfer to a 100 cc. volumetric flask; cool and dilute to the mark. Mix and pour through a dry filter into a beaker. Draw off 50 cc. with a pipette, and place in another 100-cc. flask. Add cautiously 10 cc. strong sulphuric acid and rinse it down with a wash bottle; then add 0.3 gm. powdered aluminum. Give the flask a rotary movement to stir thoroughly, and rinse down the aluminum. If the flask is too hot and acts too strongly on the aluminum, cool slightly in water. The heat should be just sufficient to insure ready action on the aluminum, but not to cause it to foam. The flask is then set aside for about 10 min., shaking it at intervals. Cool and dilute to the mark. Place a plug of absorbent cotton, firmly pressed down with the fingers, in a dry funnel and place underneath a dry beaker containing a piece of aluminum foil. Pour off the reduced molybdenum solution, containing the powder, through the cotton. The object of the foil in the beaker is to prevent the molybdenum from re-oxidizing. The solution should be run through rapidly for the same reason. It should have a clear green color. Draw off 50 cc. with a pipette, which should represent 1 gm. of the original ore, and titrate with N/10 permanganate solution. From the number of cubic centimetres used deduct 0.3 for the action of the impurities of the aluminum product (it is best to run a blank test against 0.3 gm. Al), and multiply the remainder by 0.00533 for MoS_2 , or by 0.0048 for the molybdenum oxide, MoO_3 . Continue the titration till the pink tint from the last two drops does not fade out for at least one-half minute. With ore containing 10 to 25% use only 2 gm. of the ore, and for those above 25% use only 1 gm. A small amount of aluminum running through the cotton will affect the result, and make the end point indistinct.

ESTIMATES from present incomplete exploration of the coal areas of the United States of Colombia give an available supply of over 27,000 million tons of bituminous coal. Peru has 1339 millions of tons of bituminous, and 700 millions of anthracite. Chile, according to the governmental estimates, has resources of bituminous coal amounting to 3048 millions of tons.

Secondary Enrichment of Zinc Deposits

By FRANK L. NASON

*This overworked term seems to be covered by 'aggregation' or even by 'segregation.' Leaving it at its face value so far as zinc deposits are concerned, evidence gathered from a wide range of observation points to subtraction rather than to addition, in many if not in all cases; in accounting for rich deposits of oxidized ores. The Bertha mines in Wythe county, Virginia, are excellent examples of the point in question. The surface of the worked deposit was originally covered by a thick mantle of clay. Mining disclosed pinnacles or chimneys of limestone as high as 100 ft. Some of these pinnacles were coated with oxidized ores and the 'valleys' were occasionally floored with massive deposits from 5 to 40 ft. thick. In addition, there were layers of soft and hard 'buckfat' carrying from 15 to 17% zinc. The chimneys, while showing some blende, were nowhere as a whole of economic value. In no place was there blende sufficient to account for the probable average of 15% zinc in the valleys between the pinnacles. The conclusion seems warranted that the rich mass of oxidized ore had been formed by aggregation from the blende-bearing limestone. Yet examination shows that the chimneys and floors are of dense compact dolomite with no evidence of even capillary channels, through which the solutions might have traveled. This would leave the only source of enrichment to the overlying blende-bearing dolomite. But on all sides of the old workings the surrounding dolomite is barren of zinc. There are no visible channels or sources from which or through which enriching solutions could come. The conclusion seems inevitable that the rich oxidized Bertha deposits were formed *in situ* by the subtraction of the soluble dolomite in which the zinc orebody was originally present in the form of sulphide. This conclusion was almost completely demonstrated at the Austinville mines about 8 miles south-west. These mines were originally worked for oxidized lead exclusively, later for both lead and zinc sulphides. The outcrops are about 235 ft. above the base-level of the drainage of New river. Mining here disclosed the same chimney-formation as at Bertha, and the oxidized ore was of the same character. The clay in places was 90 ft. thick. Instead, however, of the ores being confined to chimney-coatings and to floorings, at least 6 well-defined blankets of oxidized ores were followed, not continuously, for at least 6000 ft. on the strike and were down on the dip to the level of the river. At this level the original sulphide appeared to the exclusion of the oxidized ore. In other words, in repeated instances, oxidized ore was followed down to the original sulphide and this, in turn, has been followed down to the 435-ft. level, 200 ft. below the base level of drainage. The combined lead and zinc averages about 14%, large masses assaying as high as 30%. There seems to be no possible doubt that the rich oxidized ore, averaging upward of 40%, was formed

by subtraction of the dolomite, not by the extraneous addition of zinc and lead.

Another striking example is to be found at the New Prospect mine in Union county, Tennessee. This mine may be represented by a prism about 900 by 50 by 90 ft. For 600 ft. the western end of the prism consisted wholly of oxidized ore. The bottom 20 ft. of the mine is shattered dolomite assaying about 20% combined zinc and lead. For 30 ft. above this the combined metals average about 10%. Here the rich oxidized ore was derived from the decomposition of the mass in place, the result being that the soluble dolomite was, in the main, leached out, leaving the oxidized lead and zinc. This is another example of subtraction, not addition. The same conclusion is reached at the Straight Creek and Mascot, in Tennessee; the Hanover, Kelly, and Cleveland in New Mexico; the San Xavier in Arizona; the Leadville and Gilman veins in Colorado; the Tiro General, La Bufa, Cruz del Aire, and other mines in Mexico and the United States. In Guatemala and San Salvador are mines showing the same characteristics. In each of the mines cited, rich oxidized ore has been followed down to correspondingly rich sulphide. The Bertha and Delton mines in Virginia, the Embreeville, New Market, and Mossy Creek mines in Tennessee, show no commercial zinc sulphide below the oxidized surface ore even with fairly extensive drilling. Some mines in Wisconsin and in the Joplin field (in its most comprehensive meaning) seem to be examples where the subtraction has been carried to the point of exhausting the zinc and lead as well. In these instances, where masses of stained clay give evidence of the work of meteoric waters, secondary enrichment ought to have followed. On the contrary, however, these waters have removed not only the limestone but most of the zinc as well.

There is a peculiar mine near Santa Eulalia, Chihuahua, Mexico. A shaft about 1100 ft. deep was sunk through a rotted rock of undetermined origin; then came about 200 ft. of oxidized ore, then about 200 ft. of zinc and lead and other sulphides, and finally, oxidized ores again. In the zinc mines of Alotepec, Guatemala, are great dike-like masses of garnet in which zinc and lead assay as high as 16%. The galena and blende often come to the surface. In places, however, the blende is decomposed and the cavities are largely filled with zinc oxide. The mine outcrops for about $2\frac{1}{2}$ miles along the Rio de las Minas. The greater part of the ore-zone has a hornblende gangue instead of garnet. The hornblende is badly decomposed but carries zinc oxides from 3 to 11% zinc. When undecomposed hornblende is found, zinc in the form of sulphide is found in the same quantity. In the San Juan de Calera mine in San Salvador, zinc and lead are present to the extent of 39%, mainly as sulphides. The gangue is garnet and occasionally, as at the Alotepec mines, the cavities in the garnet are filled with zinc oxide. In the same district is the El Tejada mine. No blende was observed here but loose sheets of high-grade calamine were seen. These were observed in both jointing and bedding planes, flanked with

*Abstract: Characteristics of Zinc Deposits in North America, Bull. A. I. M. E. May 1917.

rotted granular masses of white limestone. The rotted planes were from a few inches to 5 ft. thick, succeeded by blocks of fresh limestone. The faces resembled masonry walls, the calamine representing the mortar. At Hanover, New Mexico, oxidized ores with rotted hornblende abut in places against solid garnet carrying upward of 5% zinc as blende, while oxidized ore also occurs in jointing and bedding planes.

Correction Chart for a 500-Ft. Tape

By WALTER SCOTT WEEKS

In response to a letter I have prepared a new chart for correcting a steel tape for sag, stretch, and temperature. This chart gives corrections for tape-lengths from 200 to 500 ft. A person who intends to use this chart should read the discussion of the theory upon which it is based. This may be found in the MINING AND SCIENTIFIC PRESS of October 28, 1916. In that article I gave a chart for correcting tapes from 0 to 200 feet.

The present chart can be used for correcting a steel tape of the specifications given in these articles.

The pull to be exerted on the tape shall be 6000 times the weight of one foot of tape. This pull will induce a unit-stress of about 20,000 lb. per square inch. The pull may be measured at either the upper or the lower end of an inclined tape.

Compute the temperature at which the tape is correct in length with no pull and entirely supported. This is the standard temperature. Use the tape with a pull that equals 6000 times its weight per foot. Subtract algebraically the standard temperature from the temperature at which the tape is used, to obtain the 'variation from standard temperature.' Place one point of a pair of dividers on the intersection of the temperature line and the length line and the other point on the intersection of the sag line and the length line, and transfer this distance to the scale at the left where the correction is read in feet. For example:

A 500-ft. tape weighing 0.005 lb. per foot is standardized at a 20-lb. pull and 60° F., and is found to measure 500.10 feet.

It is first necessary to compute the standard temperature.

The working pull is $6000 \times 0.005 = 30$ lb.

From the chart, the stretch with working-pull = 0.351.

Hence the stretch with 20 lb. is $\frac{20}{30} \times 0.351 = 0.234$.

The length of the tape with no pull would be $500.10 - 0.234 = 499.866$.

The tape with no pull is 0.134 ft. too short.

The temperature must now be raised enough above 60° to correct the length of the tape.

Raising the temperature 1° will increase the length of the tape 0.00325. To increase the length 0.134 ft. the temperature must be raised $\frac{0.134}{0.00325} = 41^\circ$.

The standard temperature of the tape is then $60 + 41 = 101^\circ$.

This is the temperature at which the tape is correct in length when entirely supported and no pull is exerted.

Let us suppose that the tape is used to measure the distance between two points; the tape reading is 440 ft., the temperature is 81°, and the angle of inclination of the tape is 70°.

The directions given above should be followed, thus

$$81^\circ - 101^\circ = -20^\circ$$

Place one point of a pair of dividers on the intersection of the temperature line marked -20° and the length line marked 440, and the other point on the intersection of the sag line marked 70° and the length line marked 440. Transfer this distance to the scale at the left where the error is seen to be 0.24 feet.

If the temperature line is above the sag curve the correction must be added; if the sag curve is above the temperature line the correction must be subtracted. In the present case the true distance between the points is 440.24 feet.

The error in the correction given by the chart is in no case greater than 0.02 feet.

A stop should be placed on the spring-balance as described in the MINING AND SCIENTIFIC PRESS of November 4, 1916, page 668, in my article entitled 'Measuring With the Steel Tape in Mine Surveying.'

RUSTING OF CAST-IRON was made the subject of a series of tests by E. A. and C. T. Richardson, in comparison with steel and pure iron. The results of seven months exposure to oxidizing influences showed that the losses of metal, computed in grammes per square centimetre of surface, were for cast-iron, 0.966 gm., for pure iron, 0.771 gm., and for steel 1.546. The cast-iron corroded in a manner similar to the pure iron, while the steel was deeply pitted, and the rusting had been quite irregular. The analyses of the test-pieces were as follows:

	Sul-phur	Phos-phorus	Manga-nese	Total carbon	Silicon	Copper
Cast-iron ..	0.059	1.02	0.48	3.26	2.40	none
Steel	0.030	0.006	0.33	0.10	trace	trace
Pure iron .	0.021	0.004	0.015	0.015	0.005	0.025

The results of this test show that the resistance of an iron to corrosion does not necessarily depend upon its purity or homogeneity, as would be indicated by the electrolytic theory of corrosion. This theory, in its present accepted form, does not explain the great resistance offered by cast-iron to corrosion. While it may be true that the initial rusting is largely electrolytic in character, other factors, such as the adherence of the rust and the protection thereby given to the metal, come into operation and outweigh any electrolytic corrosion—a conclusion that has also been arrived at by other observers.—*Trans. Amer. Electrochem. Soc.*

RIO TINTO, the oldest copper mine in the world, once worked by the Romans, and before them by the Phoenicians, last year paid to its British owners the handsome sum of £2,145,830 or about \$10,500,000. That represents an earning capacity of 95% on the capitalization of the company.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

FUEL EFFICIENCY in steam-making is the ratio between the heat absorbed by the boiler and the heat-value of the fuel burned.

INJECTION under the skin of a 3% solution of hydrogen-peroxide is said to be an effective antidote for poison by cyanide where the poison has been inhaled.

THE GRAIN-SIDE of a leather-belt should be run next to the pulley, as it adheres more closely than the shaved side, thus enabling the belt to transmit more power.

THIN ROCK SECTIONS, prepared for study under the polarization microscope, may be projected upon a screen in the same manner as photographic views in the stereopticon.

COAL CROPPINGS are often dull and earthy in appearance, sometimes of a brownish color. The coal improves in depth, though to what extent cannot be told from the surface exposure.

MERCURY BOILS at a temperature of 676° F., and at that temperature and higher it distills rapidly, though mercurial vapors will rise from the metal at a lower temperature than 676°.

ALLOYS OF LEAD, TIN, BISMUTH, AND CADMIUM are all easily fusible. One of these consisting of tin 4 parts, lead 8 parts, bismuth 15 parts, and cadmium 3 parts, melts at 55° C. or 131° F.

BOILER-FEED WATER should always be pre-heated, not only because it saves expense in making steam, but it causes much of the scale-forming minerals in the water to deposit in the heater instead of in the boiler.

COBALT has been produced at one locality in the United States in considerable quantity, namely, at Mine La Motte, in Missouri. The principal cobalt-producing region of the world at present is New Caledonia, where it occurs with nickel ores.

GOLD DREDGES are rated as to capacity according to the amount of material the buckets can dig within a stated period. Some of the larger dredges working under favorable conditions handle 3000 cu. yd. per 24 hr. Some claim to be doing more than this.

THE V FLUME in Madera county, California, is 53 miles long and cost \$270,000. It is built of scantling and boards, has 36-in. sides and is 46 in. wide at the top. It was built to float lumber from the mills in the mountains to the valley.

WATER can be heated to a temperature of 212° F. only under atmospheric pressure, and this only at sea-

level. When the water is confined so that pressure results and increases with rising temperature, the temperature can be raised to a high point.

CEMENT COPPER is the name given to metallic copper precipitated by scrap-iron from a solution of a copper salt. It seldom contains more than 60% copper. About 4 lb. of metallic iron is consumed in precipitating 1 lb. of copper in the tanks or precipitating-troughs.

BESSEMER ORE for making iron suitable for blowing to bessemer steel is one that will yield a grade of pig-iron containing not to exceed 0.10% phosphorus. While limits for the iron, silica, and sulphur-content are usually assigned, the controlling factor is the phosphorus.

QUARTZ is always crystalline but not always crystallized. Quartz is silica. The variety of silica called hyalite is not crystalline but amorphous—without crystalline form. Quartzite is metamorphosed sand-stone. Quartz occurs in the form of rounded or semi-rounded grains in granite, rhyolite, dacite, quartz-porphry, and in a few other rocks. It also occurs abundantly in certain metamorphosed sedimentary rocks, such as jasperoid rocks, and quartzite.

THE United States Bureau of Mines, has caused to be issued pamphlets on 'elementary first aid for the injured miners.' These valuable bulletins are thus far printed in Italian, Polish, and Slovak, with the English equivalent on opposite pages, the object being that miners of foreign birth may have the advantage of the necessary instruction for rendering prompt aid to those injured in mines. It cannot fail to be of value in reducing suffering and in saving human life.

COBALT is chiefly employed in making paints and enamels. Several years ago it was reported that Thomas A. Edison had discovered a new use for cobalt, and would require a large amount of the metal, but nothing has been heard of this recently. Elwood Haynes has made a remarkable alloy of cobalt and chromium, called stellite, that is extensively used for high-speed tools in lathe-work. It also has been employed for acid-proof edge-tools.

TARNISHED silver may be cheaply and efficiently cleaned by the so-called 'electrolytic method' as follows: place in a clean agate-ware dish, in which the enamel is entirely unbroken, a solution of 1 teaspoonful of soda (soda-ash or baking-soda) and 1 teaspoonful of common salt to 1 quart of water. A sheet of aluminum or clean zinc is immersed in the solution in contact with the piece of silver to be cleaned. The two metals should be completely covered by the solution. Heat nearly to boiling. When the tarnish disappears from the silver, remove it; rinse with cold water, and wipe with a soft cloth. The amount of silver lost by this method is said to be 25 times less than that occasioned by cleaning with ordinary silver-polish or other abrasives.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

MOUNTAIN KING, CALIFORNIA

THE DISASTER AT THE MOUNTAIN KING MINE.—HEROIC BUT FRUITLESS EFFORTS OF THE SUPERINTENDENT AND WORKMEN TO RESCUE THE MEN.

The Mountain King mine is entered through a cross-cut adit on the 1000-ft. level. At a point 3000 ft. from the portal is what is known as No. 3 winze, which, including the sump, descends to the 1500-ft. level. There are drifts both east and west at the 1100 and 1200-ft. levels. These are extensive and are connected otherwise than through the winze by raises and stopes. The work of sinking the winze from the 1200-ft. level to about the 1500-ft. level is a recent development and a station has been cut at the 1400-ft. level and driving east and west on the vein has proceeded some distance.

On Saturday, April 28, at 2 o'clock a.m., after the night-shift working in the 1400 drifts had finished, the faces of the drifts were blasted as is usual. From 2 a.m., until 7 a.m., when the day-shift goes in, there is no work in the mine, but it has been the practice, while working in the winze, to open a valve on the compressed-air line, allowing the air to escape, thereby driving out the smoke and gas from blasting, so that the winze and drifts on the 1400-ft. level would be clear for the day-shift.

The mine derives its power from the company's hydro-electric plant, on the Merced river, through about a mile of flume. At a place close to the power-house there was a leak in the flume. This had not been serious, but at 3 a.m. on Saturday the leak in the flume began to give trouble. The plant was shut-down and the water turned out. This caused the stoppage of the air-compressor at the mine before the smoke and gas in the winze could be blown out.

At 6 a.m. the power-house operator notified B. C. Austin, superintendent of the mine, that the power was off and requested a crew to be sent to the power-house to make a thorough repair on the flume, necessitating a continuance of the shut-down for perhaps a half day. At 6:30 a.m., Mr. Austin notified D. DuFau, the mine-foreman, that there would be no work in the mine as air and power would be off for a good part of the day and directed him to send the men who would have gone down to work in the 1400 drifts at 7 a.m., to the flume. Mr. DuFau advised Mr. Austin that he wished to repair some track in the 1200-ft. level and asked to use a part of his gang there. Accordingly DuFau sent seven men down on the flume, accompanied by Austin. Seven others went into the mine and descended to the 1200-ft. level and went to work. When DuFau gave his orders, two of the men, being the most experienced miners, expressed a desire to go down the winze to the 1400-ft. level to see how the shots had broken. As there was to be no work done there, and aside from satisfying a curiosity, there was no reason why the trip down the ladder should be made, DuFau told the men that he did not believe it would be safe to go down as the gas had not been blown out. The miners scouted the idea, but DuFau strictly admonished them to return immediately from any point where they met gas.

The gang on the flume upon commencing work, took out a section 30 ft. long.

At 7:30 a.m. DuFau joined the gang working in the 1200-ft. level and remarked that the two men who had gone down below had not returned, and he immediately went to the shaft and descended the ladder. In a short time DuFau returned and shouted that the two men were in the 1400 and were gased.

He called to a man to go up to the 1000-ft. level and if necessary out of the mine to notify Austin that two men were unconscious in the 1400-ft. level drift. The man, Benes, did as he had been directed and then DuFau called to another man, Galino, to accompany him for the rescue of the men. Before they could get to the shaft, three other miners who had heard the shouting preceded them and descended to the 1400-ft. level. DuFau and Galino may have succeeded in getting down to the 1400, but if so, they must have immediately returned as they were found lashed to the ladder, the former about 50 ft. and the latter about 80 ft. below the 1200-ft. level. In a few minutes Penes returned bringing two bottles of spirits of ammonia and immediately descended to the 1400-ft. level. In passing DuFau and Galino, he noted that they were unconscious and he gave them ammonia which revived them slightly. When he arrived at the 1400-ft. level he was faint; but constantly inhaled the ammonia. He found all five men, the two at the face of the drift, the others, where they had fallen in trying to get to the ladder, all unconscious, but alive. Although in great distress, Benes found a gunny-sack, cut it into five strips, soaked them with ammonia and tied a strip around the nose and head of each of the five men. By a superhuman effort he succeeded in dragging himself up the ladder, stopping long enough when he reached the men on the ladder to make them more secure and then climbed to the 1100-ft. level, evidently with the idea of getting to the 1000-ft. station, where he could give the alarm. He was found at the 1100-ft. level in very bad condition; but by strenuous efforts his life was saved. By this time Austin had arrived. He improvised a light car that could be lowered on a rope, lashed himself thereto and ordered the men to lower him with the idea that he could pick up one man at a time. He attempted to get DuFau, but fainted before he could cut him loose from the ladder. Three times he was lowered and three times was pulled up and revived. There were more than two score men who volunteered and almost fought to go down but Austin forbade it. A hand-pump was installed in the 1200-ft. station and all day air was pumped down the shaft and for hours a hose was played down the shaft. Meanwhile, as soon as Austin had received word of the disaster, he ordered a temporary section of flume to be constructed, but it was late in the afternoon before this was completed so it would carry sufficient water to operate the compressor and hoist, by which time the seven men had been dead for several hours.

The mine makes no gas naturally at any point, and the ventilation by natural means is perfect, except at the bottom of the winze, and this will soon have natural ventilation. Every safety-device and precaution that could be taken has been the rule at this mine, and it has been the policy of the management always to give warning of any danger to the workmen, both above and underground.

SUTTER CREEK, CALIFORNIA

RAPID RE-OPENING AND DEVELOPMENT OF THE OLD EUREKA MINE.

A LARGE ORE RESERVE AVAILABLE.—THE TAILING TROUBLE AGAIN.

At the Old Eureka mine all the water has been removed from the shaft and men are engaged in cutting out the lower part of the shaft to conform to the double-compartment above the 1700-ft. station. As formerly worked, the double-compartment shaft extended to a point about 40 ft. below the 1700-ft.

station, and from there down there was but the one compartment. The present work of cleaning out and widening the shaft is between the 1700 and 1800-ft. levels. The company has built dams on the upper levels of the mine, and provided pumping-plants of double the capacity required to handle the mine-water under normal conditions, and a large concrete dam is now under construction on the 1700-ft. level, to take care of the water at that depth. The shaft and stations are lighted electrically, a complete telephone-system has been installed throughout the mine and the surface plant; also an electric-bell system, which flashes a light underground when the contact is made, this being in addition to the usual pull-bell system, which can be used in case of emergency. Another feature much appreciated by the miners, is the piping of fresh water to all parts of the mine for drinking and other purposes. The entire mine equipment, both surface and underground, is of the best. Cleaning out and repairing is in progress on several of the old levels and considerable work has been done, particularly on the 800 and 1200-ft. levels. On the last-named level, north of the shaft a vein 36 ft. wide is in sight. As the foot-wall timbers rest against the quartz the actual width is not known. The ore in the face is all good milling rock, assaying from \$3 to \$46 per ton. The vein is believed to extend continuously up to the 800-ft. level, and so far as known, no stoping has been done between the two levels, so a large reserve of ore is apparently ready for extraction, while other portions of the mine afford encouraging prospects. At the 1400-ft. station an old car was found filled with ore, just as it was left when the mine closed down, and tools of various kinds have been picked up in a remarkable state of preservation. The old timbers, too, are generally in excellent condition, owing to their forty years submersion. The excellent ventilating system now in use has practically dispelled the peculiar odors usually observed in a mine so recently reopened and the present owners are receiving great credit for the large amount of work accomplished in a little over a year's time. A large amount of money has been expended in opening up and re-equipping this old mine, but within the next year, the owners will doubtless see actual mining operations under way, with every prospect of reaping big dividends. The Old Eureka is credited with a production of approximately \$20,000,000, and it is known that the methods in vogue during the former operation of the mine made it impossible to profitably work ore of a quality that would now yield handsome returns. In fact, only about 60% of the values could then be saved. The concentrate was then a total loss and amalgamation methods were extremely crude, so that modern methods applied to the ore now blocked out, and the probability of finding other parallel veins as the work proceeds, should insure the speedy success of this enterprise. T. Walter Beam is the general manager, and William Martin is underground foreman of the mine.

As a result of protests made by farmers whose valley lands are alleged to be damaged by the overflow of tailing, the mills of the Original Amador Consolidated Mines Co. and of the Keystone mines have been hung up and it is not yet known how matters will be adjusted.

The local miners' union, in which are represented the miners of Amador, Calaveras, and Tuolumne counties, has withdrawn from the Western Federation of Miners and will hereafter be known as the Mine Workers' Union of the Mother Lode. James Giamb Bruno is the secretary.

At the Kennedy mine a new level is being opened at a depth of 3900 ft. The East shaft has reached a vertical depth of 4012 ft. The 3900-ft. station has been cut and a cross-cut started this week to reach the vein on that level. Three new boilers have been added to the power-plant, to replace smaller ones, and other improvements are under way. The Kennedy mine, which is one of the largest producers in California, employs 390 men and the pay-roll amounts to about \$36,000 per month. Webb Smith is the superintendent.

Capt. T. Hoatson, of Michigan, and others interested in the Wildman-Mahoney property at Sutter Creek, are inspecting their property, and as one result of their visit, men are blasting out and tearing down the old head-frame over the Wildman shaft, which has appeared to be in danger of toppling over for several years past. In fact, the road past the hoist was closed several years ago, to prevent injury in case the building collapsed. Rumors of the early resumption of work there are not confirmed.

PLATTEVILLE, WISCONSIN

UNCERTAINTIES OF THE MARKET FOR LEAD AND ZINC.—MILITARY GUARDS PLACED.—HEAVY PRODUCTION.—NEW OUTFITS.

Unsettled conditions, especially affecting the spelter market, resulted in a season of lowering values on zinc-ore offerings all through the month of April. This influence was felt severely in the Wisconsin zinc field and production, under the most favorable conditions for normal recovery, fell far below that usually recorded at this time of the year. Regardless of the handicap, no abatement in exploration, mine development work, or plant-construction was shown. In every district of the field numerous drill-squads were at work testing new areas; mine development was hurried along, more particularly in the southern mining camps of the field, and new power and milling-plants were ushered into active service. Leading mine managers who were interviewed during the month confessed that still greater headway would have been made had labor conditions been more satisfactory. Wages are the highest ever known in the field. Mine foremen receive \$4 per day; miners breasting, \$3.50; trammers, most of whom labor under contract, \$4 to \$6 per day; hoist-men, \$3.50; machine-men, \$3.50; mill-men and helpers, \$3.50 to \$4; and electricians, \$4, and yet, to one thoroughly conversant with the field, there is evident the need of at least 1000 to 1500 men. This abnormal demand for help is being met to some extent by the introduction of negro miners, and scores of white miners recruited from the State of Kentucky, who arrive in bunches of 20 to 30 at a time.

All of the leading operating companies feel intuitively that war-time demand for metal will compel a quick recovery of both price and demand for zinc. Some who are better able financially than others to carry heavy investments in ore piled up in anticipation of higher prices, are content to await developments and are not shipping the current output, merely sending enough ore to market to meet the operating expenses. Where contract arrangements cover the output, deliveries are maintained at the usual rate.

Military precautions have been taken at several points in the field, where the foreign element predominates among the workers. The big works of the New Jersey Zinc Co., at Mineral Point, are under the constant guard of the State militia and the company's mines, at all points in the field, are likewise under the protection of the militia. Powder-magazines also are carefully guarded. Trusted employees have been appointed to look after stocks of dynamite and miners leaving the field are subjected to a rigid inspection of all their belongings. In not a few instances have miners' suit-cases been found to contain explosives in quantity. The Mineral Point Zinc Co. presented ten of its mines with flags 9 by 18 ft., which are flung to the breeze each morning from tall poles, and at dusk the colors are lowered and 250-kw. incandescent lamps are hoisted under large reflectors to illumine the grounds at night. Search-lights play about the mills and buildings. The Vinegar Hill Zinc Co. performed a real patriotic duty when it presented its men, in the Galena district, with \$1000 worth of seed-potatoes for planting and turned over big tracts of ground for cultivation for their benefit.

Zinc-ore prices opened up in the first week of April at \$85 per ton base, 60% assays and premium grades, with the range down to \$80 for medium and second-grade ore. While this

was considerably below the high prices for March, operators felt no apprehension of sharp declines and outputting proceeded at fairly normal capacity. The week ended April 14 brought a drop of \$5 per ton in the base-price with even sharper reductions on inferior grades, the range receding to \$72.50. By April 21 the top quotations had again been trimmed, the base-high being placed at \$72.50, with the range down to \$70. Further reductions came with the closing days of marketing for April, the base standing at \$70 per ton at the close of the month, with the lower quotations at \$65. W. M. Smith, general manager of the Vinegar Hill mines and refining-plants, when questioned as to whether or not war-time demand for zinc would bring a return of higher prices, replied that in his opinion it would not, but that he believed it would prevent further declines. This view appears to be taken by other operators in the field. Low-grade zinc-ore producers suffered as a result of the lower offerings, many being unable to market ores containing under 40% zinc. Very little low-grade zinc ore came through during the month from the small independent-operating firms that were compelled to offer their ores for sale on open-market quotations. Such ore as did come from these sources was shipped under contract, or under 'gentlemen's agreements,' but few districts were favored in this manner. There was a fair reserve of both low and high-grade zinc ore in the field at the close of the month.

Lead-ore production in the field showed little appreciable gain through April, but preparations were made at several new mines for an output that will begin to assert itself later. Prices held at the beginning of the month at \$110 per ton for 80% metal, and a good demand prevailed. In fact, some competition developed, the Mineral Point Zinc Co. placing a buyer in the field. Retrogression in the price of ore was noted about the middle of the month and the offerings fell to a point at one time under \$100 per ton. In view of the sold-up condition of the pig-lead market, and a constant and healthful tone in metal quotations, it was difficult to understand the reversal of form in lead-ore offerings. Producers who had held, notwithstanding high markets, for even better figures, had occasion to regret not unloading; as considerable ore was carried over. Prices, however, began to pick up again toward the close of the month and the 30-day period ended with lead ore back to \$110 per ton, with offerings on fancy lead concentrate at \$112. Shipments for the month were light and sales were variously distributed. The return of spring weather induced many small operating companies to invade shallow diggings where lead ore is found in the upper horizons and the Annex Mining Co., a new enterprise, provided a surface-outfit for an exclusive lead-ore producer on the Peaceful Valley Mining Co.'s lease in the New Diggings district. Lead production fell off with the lower turn-in of zinc concentrate, since most of the lead ore recovered in the field is obtained as a by-product of the wet concentration of zinc ore.

Shipments of iron pyrite showed improvement, more ore reaching the track from refining-plants. A genuine scarcity of cars during the first half of the month found refiners reluctant to use valuable cars for the loading of low-priced pyrites, and preference was shown for the high-grade zinc ore that was ready for delivery. The introduction of gondola cars for ore transportation, for the first time in the history of the field, relieved the situation greatly, all grades now going to market in open cars, the finished separator-product as well as the low-grade ore. The advantage of the new cars was shown by an entire absence of any 'claims' during the last week of the month, on account of a scarcity in cars for prompt loading. Shipments made from each source of production show that there is scarcely any competition among buyers for this class of mine output. The buying has been limited and the destination has been different with each shipment.

Producers of zinc carbonate fared as badly as those offering the higher-priced sphalerite, the lower offerings reaching all alike. The demand was off, buying being confined entirely to

the Mineral Point Zinc Co., which at present is the heaviest producer in the northern districts. Mine improvement was shown by one of the independent producers, but work was planned looking toward underground development for heavier production at a later date. The price receded from \$40 to \$60 per ton down to \$40 to \$50. Many small operators, confined to underground labors during the winter months, were busy making preparations for the summer's clean-up. Open-air plants were rigged up and good weather will see increased output this season.

Deliveries by districts for April were made as shown:

Districts	Zinc, lb.	Lead, lb.	Pyrites, lb.
Benton	23,064,000	770,000
Mifflin	5,876,000	60,000
Galena	3,640,000	152,000
Cuba City	3,342,000	2,994,000
Linden	3,056,000	60,000
Hazel Green	2,206,000
Shullsburg	2,172,000	150,000
Platteville	1,140,000
Potosi	497,000
Highland	480,000	60,000
Montfort	166,000
Mineral Point	66,000	2,766,000
Totals	45,705,000	1,252,000	5,760,000

Shipments of wet concentrate for the month from the mines to refining-plants in the field aggregated 387 cars—15,167 tons; from refining-plants to smelters, 133 cars—5115 tons; mine-run ore to Grasselli Chemical Co., 67 cars—2575 tons; in addition the Mineral Point Zinc Co. shipped to the smelter at DePue, 2691 tons of calcined blende, bringing the total net deliveries for the month out of the field to 10,381 tons. This is regarded as being 3000 tons under the normal capacity; but it was difficult to establish a reserve in the field at the close of the month compatible with this figure.

The gross recovery of mine-run output for the month totaled 16,204 tons, which was considerably under the figure obtaining ordinarily, the shortage being estimated at 5000 tons. The introduction of new mines and mills makes it obvious that production had been curtailed.

A hasty survey of the field, taking into account the more noteworthy events occurring within it during the month, proves that it was a busy time. The Mineral Point Zinc Co. resumed operations at the Red Jacket mine, in the Centreville district. At the Highland-Kennedy mine a new well-bore at a depth of 500 ft. was tested for water for milling and was found deficient. A new surface-rig has been waiting upon the outcome of this development for more than a year and 60 miners are meantime denied employment. The O. P. David mine, at Montfort, has suffered serious mishaps. A walk-out of the men, who demanded better pay and shorter hours, was followed by the discharge of the entire crew, who were later replaced by a new outfit. A friendly tussle among miners in the change-house at one of the mines at midnight resulted in the explosion of a box of detonating caps, causing the death of one miner and the serious injury of seven others. Linden operators appeared before the State Railway Commission with a demand for more adequate power from the Mineral Point Public Service Corporation, declaring that there had been interrupted working-schedules because the capacity of the power-line did not meet the demand made upon it. Dodgeville district reported a new project with mill-building, to be known as the North Survey Mining Co. The Utt-Thorne Mining Co. secured the Pierson and McIlhon leases, in the Mineral Point district, and resumed operation in the Harris mine, restoring the mill-equipment. All three leaseholds will be operated through one central plant. Mifflin showed new mine development on the Dale Rundell farm, the output of which will be

combined with the Yewdall and Senator mines. The Utt-Thorne company discovered heavy zinc deposits in the mine-floor and have opened up for increased output. New strikes were made in the Platteville district for the Block-House Mining Co., which at the end of the month was holding \$100,000 worth of choice dressed ore, demanding better prices. New mill-building was well along in the Cuba district for both the Standard Metals Co. and the G. O. P. Mining Co. The east wing of the Linden zinc refinery was destroyed by fire. New machinery will be installed at the National Separators to collect dust and gas-fume. Benton district made its usual fine showing and introduced a new shipper to be known as the Middie. The Strawbridge Mining Co. began the construction of a new power and milling-plant; the Vinegar Hill company has a new shipper with complete new surface-rig, to be known as the Meloy mine. The Northwestern railway began the construction of a branch line from Strawbridge to New Diggings, causing a building boom in the village, among mining companies and adjacent zinc-mining districts. Hazel Green district showed new development on the McMillan property that resulted satisfactorily after a new plant had lain idle for a year because of the failure in determining the main-range of ore when the mine was first opened up. The Rio Mining Co. has also developed a new lease showing big deposits.

The Wisconsin Zinc Co. dismantled its equipment at the Birkbeck mine in the Galena district and removed it to the Copeland mine, at Shullsburg, where it is being re-built. The Vinegar Hill Co. has supplied a new surface-rig to the Jefferson mine and the old works were squared up and put in working order. Water-pockets that were broken into at the Graham mine drowned out the miners, and required heavy pumping for two weeks at the rate of 3000 gal. per min., when operations were again resumed. The Wisconsin Zinc Co. finally has abandoned the Galena-Joplin separators, claiming that the plant was run down and could not stand up under the demands made upon it. It is owned by the Picher Lead Co. The Potosi district showed two companies in fair producing shape, the Wilson and Tiffany, both of which prepared for increased output. Drill-squads working for the Tiffany Mining Co. made rich strikes of both lead and zinc ore on adjoining leaseholds.

COBALT, ONTARIO

ORE RESERVES OF THE PETERSON LAKE DEPLETED, AND DIAMOND-DRILLING RECOMMENDED.—HIGH-GRADE ORE IN THE RAND CONSOLIDATED.—LA ROSE PRODUCTION FALLING OFF.—NIPISSING STILL HAS LARGE ORE RESERVES.—THE CROESUS MINE RICH IN GOLD.

The first quarterly statement, sent out to Peterson Lake shareholders since the new management assumed control, announces that the usual quarterly dividend of 1½% will be passed. The company has paid to shareholders to date \$462,191. The reason for passing the dividend is found in the report of the consulting engineer, Frank C. Loring. This report states that the company has very little ore left to stope, but recommends further development and exploration by diamond-drilling, and the extension of the work on the present known veins, particularly in No. 2 shaft. S. G. Forst has been appointed managing director and W. A. Lamport, secretary-treasurer of the Peterson Lake Mining Company.

The Rand Consolidated Co. during the last week has moved a small steam mining-plant to its copper prospect in Strathy township, in Temagami forest reserve.—The annual meeting of the Beaver Consolidated Mines was held at Toronto, on April 24. In the annual report of the company, president Culver says of the new vein discovered at the lower contact of the diabase-sill on the 1600-ft. level of the mine: "This vein is six to eight inches wide, rich in silver, and on both sides of the vein for about four feet the wall-rock is heavily impregnated with leaf-silver. The discovery has caused a great deal

of interest in the Cobalt camp, and while we are not yet in a position to say to the shareholders that it will actually make a new mine out of the Beaver, it is most encouraging."

The report shows the earnings of the mine for the year to be \$499,690 from an output of 746,310 oz. of silver. Operating charges were \$245,004, leaving a profit of \$236,582, as against \$128,929 in the previous year.

The annual report of the LaRose Consolidated Mines indicates a marked falling off in the production of silver at that property. During the year production amounted to 740,065 oz. of silver with a net value of \$449,734, the treatment of which resulted in a net profit of \$164,774. Since the commencement of mining for silver from the LaRose, thirteen years ago, the company has paid a total of over \$7,000,000 in dividends. The mine reached its maximum of production in 1911, during which year approximately 4,000,000 oz. of silver was recovered. The company carried into 1917 a surplus of \$727,169. Operating costs during 1916 were 46.39c. per ounce, as against a selling price of 64.89 cents.

Nipissing, as shown in the annual report recently issued, continues to lead all of the other silver mines of the Dominion. After having paid \$1,500,000 in dividends during 1916, a surplus of \$1,980,126 was carried forward into the current year. Ore reserves are estimated at 9,153,000 oz. as compared with 8,921,718 oz. the preceding year. Net profits were \$2,028,866 as compared with \$1,187,970 the year previous. The reason for this remarkable increase was the higher price received for the product.

The Croesus mine, at Matheson, Ontario, from which \$120,000 in gold was taken in the sinking of the first 100 ft., and which is recognized as one of the spectacular gold mines in the world, has this week made another important strike in a cross-cut on the 300-ft. level. The newly discovered parallel vein, as so far determined, appears to be of great importance. The formation is basalt and for a width of several feet from the fissure is said to carry a high average gold content.

Never before in its history has mining operations in the Cobalt district been conducted with greater vigor than at present, and were it not for a lack of skilled labor, the 1917 production would probably constitute a record in value. In point of ounces, production is steadily falling off, having reached the zenith in 1911, during which year upward of 30,000,000 oz. of silver was produced. At present, despite the labor difficulties, production is being maintained at the rate of about 20,000,000 oz. annually. During 1916, Nipissing alone produced over 4,000,000 oz., valued at over \$3,000,000, and of which over \$2,000,000 was net profit. Flotation is now playing an important part in the treatment of low-grade ores at the various Cobalt mines. At the McKinley-Darragh, a force began this week excavating for foundations for a new oil-flotation mill. The plant will have a capacity of about 250 tons daily, and it will be equipped with a Marathon mill, in which the tailing from the stamp-mill, which has been deposited in the lake, will be dredged, re-ground, and sent to the flotation-cells. A drag-line excavator will be employed in recovering the sand from the lake-bed. The installation, it is anticipated, will be completed about the middle of August. Among other plants using the flotation-process are the Buffalo, with a plant good for 600 tons daily; Nipissing, an experimental plant of 300 tons; Northern Customs, 200 tons; Dominion Reduction, 100; Coniagas, 100 tons; and a number of smaller experimental plants.

At the 1600-ft. level of the Beaver and Temiskaming (at the lower contact) the results are encouraging. Although the work done is insufficient to determine whether or not a new mine has been tapped at that depth, one thing seems certain, and that is that the expense of driving through about 1000 ft. of barren rock (the unproductive diabase sill) will not have been in vain, the management being reasonably assured of returns sufficient to cover the cost of the operation, with every indication of a much greater reward.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

At the next meeting of the Alaska Mining & Engineering Society the subject of discussion will be the milling-process and underground operation of the Alaska Gastineau Mining Company.

ARIZONA

MOHAVE COUNTY

(Special Correspondence.)—Nearly 50 properties, exclusive of small prospectors' operations, are now working in the Chloride district, and several others are to begin work before the middle of May.

The Steffy custom-mill should be running in less than six weeks. An initial capacity of 250 tons has been arranged for, and contracts for more than double its capacity have been offered. Small property owners will be encouraged, and, wherever possible, will be given the preference, to encourage mine development in the district.

Jesse Knight's Bullion Hill is ready to start sinking when the power-line is completed. All the machinery is in place. Poles for the power-line have been distributed and work will start inside of 10 days.

The Payroll mine is again in operation. This time it is under a 10-years' lease to L. F. Martin, of Calxico. The south drift on the 400-ft. level will be extended 250 ft. farther. Good milling-ore has been opened up in this drift.

J. E. Carter has taken the Tuckahoe mine under lease and option and is having a hoist installed. The head-frame is up and all is in readiness to start sinking a new shaft. The property is an old producer. Mr. Carter has also taken over, under the same conditions, the West Star, which end-lines the Tuckahoe on the south, and is having a hoist put on the old 60-ft. shaft, which will be sunk to 200 ft. The vein shows up well where exposed.

W. P. McKay and J. J. Robertson are operating the Puzzle group and have ordered a hoist and compressor. Until its arrival the shaft is being sunk with a windlass.

The Merrimac, an old producer, is being re-opened by J. C. Rankin. A 9-hp. hoist has been installed. A new shaft is being sunk some distance east of the old one.

The company operating the Schenectady has contracted for 200 ft. of sinking. The contractors began at the 175-ft. level and have sunk 50 ft., following the vein. Two feet of good mill-ore has come in at the bottom. Bulkley Wells, of Colorado, is one of the principal owners.

Sinking has been resumed in the Rattlesnake shaft, which is down 80 ft. on the incline. A carload of ore, taken out near the shaft, is in the bins.

The Schuykill shaft is nearing 800 ft. depth. No cross-cutting has been done since the shaft passed the 500-ft. level, above which a large tonnage of mill-ore has been developed. The company states that if the vein is found as expected on the 800-ft. level, mill construction will be commenced.

The Emerald Isle is bringing in a power-line to its plant and will, in a short time, be producing electrolytic copper. At the present time the leaching-plant has a capacity of 70 tons of ore daily.

The Gold Back has opened up 7 ft. of ore on the 150-ft. level that assays \$24.22 per ton. Arrangements are being made with the new Steffy custom-mill for treatment of a part of its product.

The Tennessee is shipping about 200 tons daily, much of it

from the 1600-ft. level, where shipping ore has been opened up carrying an ounce of gold, 15% zinc, and 8% lead.

The Copper Age mill is nearly ready to start, all the machinery having been installed. Belts are being adjusted and the machinery is being put through the usual trying-out process.

The Copper Age mine has opened up the vein for 90 ft. in each direction from the bottom of the 137-ft. winze that was sunk in the upper adit. Good ore of a milling grade is being developed. The main working adit is in 400 ft. and is opening up an ore-shoot, the extent of which remains to be proved.

Chloride, May 7.

Six cars of ore shipped recently from the Elkhart mine, at Chloride, to the smelters has returned a net profit of \$5000. The shipment included both high-grade ore and ore of a class that is usually concentrated at the mine before shipment, but, as yet, the Elkhart is not equipped with a concentrating-mill.

CALIFORNIA

The supervisor of the State for oil and gas reports for the week ended May 5 as follows: New wells commenced, 16, making a total of 388 since January 1; 32 water shut-off; 14 re-drilling or deepening jobs, and 14 abandonments.

NEVADA COUNTY

(Special Correspondence.)—Unwatering of the Allison Ranch mine has progressed to a depth of 260 ft. and two electric-pumps are clearing the shaft at the rate of 1800 gal. per minute. Repairs have commenced and within 30 days the management expects to start mining in the upper levels. The mill is rapidly nearing completion and will be ready for service when stoping starts.

Ten more stamps have been placed in operation at the Golden Center, making 30 in all. Construction of the cyanide-plant is progressing rapidly, with most of the machinery in position. Considerable work is going on from the 1000-ft. level and within a short time it is planned to start vigorous development of the Peabody mine, at Grass Valley, from the vertical Golden Center shaft. The Peabody adjoins the Gold Hill mine, which is owned by the North Star Company.

It is rumored here that early work on the old Conlan mine is under consideration. The property has been idle many years, but at one time yielded much rich quartz.

New capital has been interested in the Black Bear mine, four miles below Grass Valley, and it is announced that development will be urged with redoubled vigor. The property contains some ore of milling grade, and several small deposits of rich quartz have been found. A small mill and other equipment are on the ground.

Prospecting of the tailing deposited by pioneer hydraulic operations is proceeding at Cherokee, both with drills and prospect-shafts. Besides tailing vast bodies of gravel still in place are receiving attention. Some of the ground is said to be suitable for dredging. It is understood at Cherokee that the Guggenheims are financing the work.

Grass Valley, May 9.

TUOLUMNE COUNTY

(Special Correspondence.)—After several months of preparatory work everything is in readiness for beginning the development of the Confidence mine to a much greater depth. It is stated that sinking will be continued until the incline shaft, now down 800 ft., has reached a depth of 1600 ft. Driving

will proceed at the same time. To carry out the plans it will be necessary to increase the working force, which now numbers 15 men.

Equipment for operating the Monarch gravel mine in a practical and economical manner is being installed. The milling-plant will be ready for operation by May 15. Though the adit has not yet reached the principal objective point, gravel that can be mined and milled at a profit has been uncovered. Theodore DeMauris is superintendent.

A shoot of ore assaying from \$10 to \$40 was uncovered in the Duffield mine, near Arastraville, last week. The vein is from a few inches to 18 inches wide. The property was recently bonded to F. Cauldfield. The Duffield mine is east of the Dreisam and on the opposite side of the hill. All of the veins in this hill are repeatedly faulted.

Development work is being vigorously urged in the Shawmut, at Jacksonville, by the Tonopah-Belmont Company. Progress in sinking has averaged, it is said, 25 ft. per week.

Sinking is to be resumed at the Dutch mine at Quartz. The work of straightening and repairing the shaft was begun last week. In the short time since sinking was begun the three-compartment shaft at the Yosemite mine, adjoining the Rawhide, has reached a depth of 150 ft.—Operations have been suspended at the Columbus mine, near Cherokee, a mile and a half north of Tuolumne.

W. S. Fagan, J. A. McAllister, and L. L. Cofer have taken an option on the F. J. Munn ranch, on Moccasin creek, and will shortly begin work on a large vein that traverses the property. It is said to contain copper.

Sonora, May 9.

COLORADO

BOULDER COUNTY

(Special Correspondence.)—The Denver-Boulder Tungsten Development Co., composed of mining men of Denver, which has been operating on Lee hill, has planned extensive development on the big dike in which the iron tungstate occurs. The property consists of ten locations, and, like the tungsten district farther west, the veins carry gold—in many places in sufficient quantity to make them profitable for the gold alone—and the ores of both gold and tungsten are frequently found in close association. The officers of the company are, Dwight S. Young, president and superintendent; Frank E. Wise, secretary; and G. P. Howard, vice-president and treasurer. The property will be under the management of S. V. Coffman, of Boulder. Development is being urged on the Swarthmore adit west of the General Lee group. This property is owned by Ohio capitalists.—Mrs. S. A. Martin, who owns the General Lee group, is negotiating with Denver people for the sale of the property.—The Revenge owners contemplate the erection of a mill at their property on Last Lake.—John A. Wilson has a large vein of medium-grade ore in the Lonesome group. He is interesting capital for the erection of a mill.—Wilson Davis will commence operations on the Last Lake Company's mine about the middle of May.—A large vein of silver-lead ore will be opened up on the Otto Victor property on Tennessee mountain, when the cross-cut adit now being driven reaches the objective point. Mill-runs of ore from the vein have returned good value in lead and silver.—J. D. Kohlman, it is reported, will place a mill on the Big Group this season.—The Highland Mary Mining Co. will soon commence work in its adit near Hesse. The proper type of machinery to be erected is being considered by the owners, Bauer and Black.—It is reported that Mr. Woods, of New York, soon will resume work on his holdings in this district.—P. M. Spratt's property is increasing in value as work progresses.—The flotation process is attracting a great deal of the attention of the mine owners in this district, and it is believed that it will solve some of the difficult metallurgical problems of Boulder county.

Eldora, May 8.

JEFFERSON COUNTY

R. B. Moore, in charge of the Golden station of the Bureau of Mines, states that the laboratory there is practically completed. The whole laboratory is planned to handle any rare-metal ore involving any of the following treatments: fusing, roasting, reducing, leaching with any acid dilute or concentrate, leaching with any alkali or salt solution. Any amount of ore from 50 to 500 lb. can be handled. In addition, there are two small leaching-outfits; one for acids and one for alkalis, whereby 5 to 10 lb. of ore can be tested.

IDAHO

BONNER COUNTY

A new company has been organized to operate the Keystone mines on Lake Pend Oreille, known as the Armstead Mines, Inc. H. H. Armstead is president, A. H. Burroughs and Karl Jungbluth, vice-presidents, H. D. Kingsbury, treasurer, and H. L. Brown secretary. It is said there are available 70,000 tons of \$25 ore, the value being chiefly in silver. The mine was formerly a shipper. A long adit has been driven from near the lake-level, and this is to be driven to the vein. A large amount of equipment, including pipes, rails, engines, cars, Leyner-Ingersoll compressors and drill-sharpeners, has been delivered at the mine. The adit is in 1400 ft. and will be driven 2200 ft. farther where it is calculated the vein will be reached at a depth of 1600 feet.

MICHIGAN

HOUGHTON COUNTY

(Special Correspondence.)—If the present rate of earnings is any criterion there is every reason for the belief that the Trimountain mine of the Copper Range Consolidated will approximate a million and a half in net earnings for 1917, basing the prediction on a 27-c. copper-market average for the year. And the average is better than 31c. for the first six months of the year. The most pleasing thing about the Trimountain property is the success which has attended this property in the past three years in underground openings. From the time when Trimountain became a part of the Copper Range it has been a question as to whether it could make good or not, and the profits have been exceedingly small. In 1909 there was an actual deficit of \$47,841, notwithstanding the fact that the rock tonnage was just about the same as it was in 1916 when the profits were \$1,236,048. Of course the price received in 1909 was 13c. and the price received last year was above 25c., but the real difference shows in the improved grade of rock. The mine yielded 16 lb. per ton in 1909 and 25 lb. per ton last year. For a period of four years from 1908 to 1912 the earnings were averaging under \$50,000 a year and then the turn came and Trimountain changed from a questionable commercial property to an assured mining success. The management is entitled to great credit for this change, because the introduction of better underground systems resulted in a closer selection of rock, a more careful avoidance of poor stretches, and an intelligent use of every advanced mining idea.

Houghton, May 1.

MONTANA

LEWIS AND CLARK COUNTY

(Special Correspondence.)—The Rock Rose shaft of the Cruse Consolidated company has developed beyond expectation on the 200-ft. level. A good vein of silver-lead ore running from \$30 to upward of \$100 per ton in gold, silver, and lead was unexpectedly discovered in driving for the east ore-shoot opened on the level above, after cutting through a heavy fault-zone. The strike has attracted more attention than any recent development in the Grass Valley district. At the Looby shaft of the company sinking continues on ore and shipments of ore taken from development continue to be made to the smelter. Preparation for sinking to the 300-ft. level of the

Rock Rose are under way and the work will be resumed in a few days.

At the Helena mine of the Helena Mining Bureau, in the same district, the shaft is being sunk on the vein to the 300-ft. level, and shipments are made as the ore comes up. Five shafts are in active operation in a small area in the Grass Valley district, with a sixth about to be started. All these operations are on ore and the outlook for a large and deep mining district is promising.

At the Scratch Gravel hills, the Julia mine has placed a steam-plant and is re-timbering the shaft. Shipments from this development, and from a small stope, have kept the Home syndicate, which is operating the property, in funds for development and equipment with something to the good. This is a gold producer. The shipping ore averages 1 oz. gold and a total of \$28 per ton. Much milling ore carrying from \$5 per ton gold, and upward, is in reserve.

Helena, May 6.

(Special Correspondence.)—The old Drumlunnon mill, now controlled by the St. Louis company, has resumed operation and is running steadily and satisfactorily. This plant was equipped with electric-power during the past winter and changes have been made throughout for economy and greater efficiency. Ore from the old stopes and caves is being run. In the mine development is under way to reach known orebodies and to further prospect virgin ground. Two shifts were put on during the past week.

The Barnes King Development Co. had two of its best month's runs in March and April. Development in the Gloster mine of this company has given encouragement for the further development of new territory and has aided materially in the recent returns. At the company's Shannon mine the shaft has been sunk to the 500-ft. level, 300 ft. below the adit, and sinking has been resumed for the 600-ft. level. This mine continues to produce and develop well. An accident at the loading-terminal—a runaway bucket coming down the steep grade leading from the terminal—caused the serious injury of two men, but both are improving and will recover.

Deep snows have delayed much field work in this district, the condition of the roads being more than six weeks behind last year, itself a late opening.

On the Marysville Gold property, development continues on ore at several faces with a large tonnage blocked out, having an estimated milling value of \$1,500,000. The principal development is east of and adjoining the Shannon, in the old Blue Bird mine. High-grade ore has been found in the Mt. Pleasant, north of the Blue Bird. This will be reached by the Blue Bird and Hickey cross-cut, now approaching this ore-zone. A heretofore unknown vein was recently cut in the Hickey cross-cut and driving east has been commenced on this. It lies in the course of the Spokane vein, under development on the north side of the mountain. If it proves to be the same, the development on the Spokane at 400 ft. greater depth will penetrate the south area between the two developed zones. No plans have as yet been made for installing a mill for these properties.

Lessees will start work on the Bell Boy, an early-day producer, as soon as snow will permit getting in. Surveys have been made and an adit will be run to tap the ore of the Gleason Fraction and the west end of the Bell Boy.

Marysville, May 6.

NEVADA

ESMERALDA COUNTY

Eighteen inches of high-grade ore, yielding assays up to more than \$500 per ton, is showing in the new drift above the 880-ft. level of the Jumbo Extension mine at Goldfield. This drift is being extended from an incline raise that was driven back into the Velvet claim of the Jumbo Extension from the workings of the adjoining Jumbo Junior, where the rich ore-shoot was discovered and where a carload of shipping-ore has been

broken lately by the latter company. There is a good prospect of a steady production from this strike.

The rich ore is being broken separately, leaving the waste and ore of lower grade to be handled in the future.

HUMBOLDT COUNTY

A new strike of gold ore is reported from National in the northern part of the county. According to the *Lovelock Review-Miner*, the strike was made on ground not previously located, on the west slope of Auto hill, down near the foot of the range. A shaft is being sunk on a vein 4 ft. wide that assays up to \$80 per ton, mostly in gold. It is said to be at or near the contact of rhyolite-porphry and a dike of latite.

Eighteen horses, hauling four heavy wagons and a trailer, are freighting antimony ore into Lovelock from the Antelope Springs antimony mine, in Coal canyon, a few miles east from here, says the *Lovelock Review-Miner*. The team is said to be the largest ever used in hauling ore in this vicinity, and is pulling 20 tons per trip.

The hauling will continue for several weeks, until enough ore to complete a shipment has been brought in. Although the destination of the shipment has not been announced, the ore is to be shipped to the Atlantic coast.

This is the first important antimony shipment from this part of the State since antimony dropped in price.

Three shifts are being worked on the Mazuma Hills mine, in the Seven Troughs district, under bond and lease to the Helen Betty Mines Co., that is also operating the Darby mill. Two shifts have been worked previously.

Reports coming from the property are to the effect that the rehabilitation and unwatering of the old property is well under way, and encouraging prospects are being found as the work progresses.

The old Darby mill has been put in good condition, and additions and improvements to increase its capacity have been made.

LINCOLN COUNTY

Ore shipments are being made to the extent of about 250 cars monthly. The principal shipper is the Prince Consolidated. Other shippers are the Nevada Copper, Hamburg, Hodges-Cook, and Con. Nevada-Utah.

The Hamburg has declared a dividend of \$8000, payable May 21. It is reported that another dividend will be paid in June. There is said to be \$40,000 worth of ore broken in the stopes ready for shipment.

NYE COUNTY

(Special Correspondence.)—The development work on the third level in the White Caps has made average progress during the past week. The east drift has been extended 35 ft. The face is still in calcareous shale with some stringers of calcite showing. The west drift has made 37 ft. during this time. Some lime is showing although not in place, being drag from the faulted zone. The face of the west drift is still in faulted material. On the fourth level, the timbering of the sump has been completed. The new hoist has been installed on the station and everything is ready to commence sinking, as soon as shaft-timbers reach the mine. The hoist for the sinking is a 24-hp. electric, of Hendrie & Bolthoff type. Several needed improvements have recently been made in connection with the surface-plant. A Denver rock-drill sharpener has been placed in the blacksmith-shop. This machine will sharpen 100 drills in a half hour when operated at full speed. It is the intention of the management to purchase the steel in future, and make up the drills needed in the shop, as with the sharpener the drills can be made up in less time than it takes to sharpen a machine-drill by hand. The old transformer-house has been torn down and a new iron structure built around the transformers. A much needed safe-guard is an automatic circuit-breaker above the transformers, also put in. In case of a surge of current on the high-tension power lines, this circuit-breaker will protect the transformers from a short-circuit and

fire. Two cooling-tanks, with a capacity of 14,000 gal., to cool the water for the two compressors have been added to the surface equipment. These tanks are connected with pipe-lines and hose, so that adequate fire protection for the mine buildings is always ready. The centre column for the Wedge roaster has been put in place. The column is 25 ft. 5 in. high, 5 ft. diam., and weighs 14 tons.

Steady work in sinking the shaft has been progressing during the week at the Morning Glory. Good progress has been made, although some repairs to the hoist have delayed the sinking from being done at maximum speed. Two shifts are employed.

Development work from the 600-ft. level in the Amalgamated for the past week is as follows: The east drift has advanced 47 ft., making a total of 145 ft. The west drift advanced 23 ft. during the week, and is now out 119 ft. from the shaft. The south drift, in a fissure vein, is now out 19 ft. The raise on the fissure is up 10 ft. For 70 ft. the west drift is in mill-ore 5 ft. wide. The face of the drift is in solid ore. The fissure shows 3 ft. of ore averaging \$20 in gold. The east drift is following a lime-shale contact.

At a meeting held May 2, which was attended by the local mine and mill-managers, of every property employing men in the camp, after thoroughly threshing out the pros and cons of the wages paid at Manhattan, a uniform wage-scale was adopted. The new scale is to go into effect not later than May 10. The scale is as follows: For miners in shaft-work, \$5 per shift for hand-work, \$5.50 for machine-work. Machine-men, \$5; timbermen, \$5; shovelers, \$4.50; cagers, \$4.50; pump-men, \$5; timber-framers, \$5.50. For surface employees, engineers, \$5 per shift, with the understanding that if engineers also help to frame timbers, or to sharpen steel, that they be paid an additional 50c. per shift. An additional 50c. to be paid should engineers be employed in the operation of double-drum hoists. General blacksmiths are to be paid \$5.50; tool-sharpeners, \$5; blacksmith-helper, \$4.50; machinist, \$5.50; machinist-helper, \$4.50; carpenters, \$6; timber-framers, \$5.50; ore-sorter, \$4; top-men, \$4; laborers, \$4; electricians, \$5; pipe-men and track-men, \$5. The scale for mill-employees will be announced later.

The first round in the cutting of the station at the 312-ft. point in the shaft at the Consolidated property was shot May 3. The bottom of the shaft is 320 ft. deep, the additional depth below the station being for sump. As soon as the station has been completed, a cross-cut will be extended, through the vein, then the shaft-sinking will be resumed to the 400-ft. level. At the point where the station is being cut, the shale is loose, with large fractures and full of quartz stringers. All indications point to the close proximity of the vein. Due to the fact that no water of consequence has thus far been encountered, it is believed that the inflow will be negligible, even after striking the vein.

Manhattan, May 8.

L. G. Burton, of Salt Lake, is at Ophir canyon in the Toiyabe range, 60 miles south of Austin, to commence operations on the old Murphy group of mining claims, which produced a large amount of silver ore in the '70's. This property is owned in Chicago and Mr. Burton and associates have a lease and option on the same. The new company will be known as the Nevada-Ophir. A great deal of work has been done on the property, which, considering the lapse of time, is in a fairly good condition for early production. Two shifts will be put to work and as the old workings are cleaned and opened up more men will be added to the force.

STOREY COUNTY

The Comstock-Phoenix mine in the East Comstock district has shipped another car of high-grade ore to the Hazen sampler. The ore has an average value of over \$300 to the ton. George H. Drysdale, the superintendent, states that the preliminary work is practically completed and sinking to greater depth will begin within a day or two. The winze is to be sunk

an additional 250 ft. to the 800-ft. level, where extensive exploration will be carried on in the ground below the stopes that have yielded handsomely in the past. The present deepest level is the 550. This section of the Comstock has never been opened at great depth.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—At the Pacific mine the 500-ft. level has been advanced 700 ft. north and the 600-ft. level is out 200 ft. in the same direction. A new vein, carrying copper, gold, and silver, has been cut in the southern part of the property. All of the old ore dump at the north end of the mine of sufficient value has been packed to the terminal-bins of the aerial-tramway to the Socorro mill and has been treated in the latter plant, and the dump at the south end is being disposed of in a like manner. In addition, stoping is under way above the adit-level.

The Oaks Company has increased its crew at the Maud S. mine and is shipping ore to the Socorro mill. Unusually good mill ore was found the past week.

H. J. Evans is starting work on the Iron Rule claim in the southern part of the district. The lower adit is to be advanced. It is on the same contact and much deeper than the Iron Bar claim, which has produced shipping-ore. For the amount of work done this section of the district is showing up favorably.

The Deep Down shaft has been re-timbered to the creek-level, a station put in, and bulkheads are now being completed. The shaft will be sunk to the 500-ft. level and drifts extended east and west. From this opening the Maud S., Eberle, and Clifton will be developed, as the shaft is centrally situated, making the plan an economical one for the exploration of the several properties, all of which are under control of the Oaks Company.

Mogollon, May 6.

OREGON

JACKSON COUNTY

(Special Correspondence.)—Alfred Lewis, of Gold Hill, who has charge of the development of the Mountain King quick-silver mine, north of Gold Hill, reports that the richest ore yet found in the mine has been uncovered this week. Carey Edmonds, a miner employed in the mine, while off shift prospecting through curiosity, made the strike. He found very rich panning-dirt on the surface on the strike of the main vein, 1500 ft. east of the works. Digging down two feet from the surface, he struck the main vein, 15 ft. across, which averages 35% mercury. Four additional adits extending 100 ft. from the discovery along the vein shows the same grade of ore. It is reported that J. R. Hayes, of Detroit, Michigan, owner of the property, will have buyers on the ground in the next few days, who will also buy 300 acres of adjoining patented land, making a total of 900 acres.

Gold Hill, May 4.

UTAH

TOOELE COUNTY

At present four mines are shipping from the Deep Creek district. They are the Western Utah Copper, Pole Star, Woodman Gold Mining, and Yellow Hammer. The Western Utah Copper, owning the old Glory Hill, has been shipping as much as 200 tons daily. The heaviest single day's production was 250 tons. The Pole Star has been shipping some of its best grades, and the Woodman making occasional shipments. Dutch mountain and Erickson districts are about to begin shipments.

In the camp of Ferber, 10 miles to the west, reached from Erickson's Ranch station, several properties are in shape to ship on a small scale. The Ferber Copper has been shipping, while some of the old properties are said to have good grades of copper ore broken and blocked out that should stand ship-

ping now that the railroad is within a dozen miles, with a good wagon-road between.

N. A. Dunyon of the Western Mines Development Co. has gone to Ferber to take charge of that property, which embraces the old Big Chief. It is expected that this company will join the shipping list shortly.

JUAB COUNTY

The Chief Consolidated Mining Co. for the first quarter of 1917 reports as follows:

Work and production at the mine:

Drifts, feet	3368
Raises, feet	469

Total, feet

Pinyon Peak Tract:

Drifts, feet	924
--------------------	-----

Plutus Mining Company:

Drifts, feet	270
--------------------	-----

Total of all development work:

Drifts, feet	4562
Raises, feet	469

Total, feet

The total shipments of ore were 19,566 tons (dry) yielding net after the payment of smelting, transportation, and sampling charges, \$451,616.40.

Metal contents:

Gold, ounces	2,690
Silver, ounces	406,199
Lead, pounds	4,232,335
Zinc, pounds	93,260

Zinc-lead ores:

Zinc, pounds	90,511
Lead, pounds	66,170

Assay value:

	Per ton
Gold, ounces	0.1375
Silver, ounces	20.76

WASHINGTON

STEVENS COUNTY

The Chloride Queen group of mining claims on Clugston creek 12 miles north of Colville are to be developed this year. It is reported that a concentrating-plant of from 50 to 100 tons capacity will be built at a cost of about \$20,000.

MEXICO

CHIHUAHUA

The Santa Gertrudis Company, Ltd., reports for March as follows: Ore milled, 19,549 tons; estimated profit, £7853.

KOREA

The clean-up for March of the Oriental Consolidated Mining Co. was \$147,705.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

D. M. RIORDAN is at Hanover, New Mexico.

L. B. NEWBY of New York is in San Francisco.

HOWARD D. SMITH has returned from New York.

THOS. H. LEGGETT has been examining mines at Butte.

KWONG WA, a mining engineer with the Ministry of War, is in San Francisco from Peking.

R. E. ADAMS, formerly at Velardeña, Mexico, is at Park City, Utah.

FRANK W. OLDFIELD has returned from New York, on his way to Jalisco, Mexico.

LEWIS E. FOSTER has opened an office as consulting engineer at Gila, New Mexico.

RALSTON WILBUR, mining engineer, has joined the Officers' Reserve Corps and is at the Presidio.

F. L. THOMAS, manager of the Leonesa mine, in Nicaragua, is here on his return from New York.

M. H. KURLA has received an appointment with the U. S. Smelting Company at Silverton, Colorado.

FRED. HELLMANN sailed for Chile, going to Chuquicamata, on May 5, and expects to return in September.

HENRY H. ARMSTEAD is president of the Armstead Mines (Inc.) operating the Keystone mines on Lake Pend Oreille, Idaho.

ERNEST WITTERNAU has been appointed assistant superintendent of concentration for The Arizona Copper Co. (Ltd.), at Clifton and Morenci.

FRANCIS S. SCHIMERKA has been appointed research engineer for the milling department of The Arizona Copper Co. (Ltd.), at Clifton and Morenci.

F. K. BRUNTON, formerly metallurgist and assistant superintendent of the British Columbia Copper Co., is now superintendent of the Consolidated Arizona Smelting Company.

FOREST B. CALDWELL has returned to San Francisco from Manhattan, where he has been elected a director and retained as consulting engineer for the Morning Glory Company.

PHILIP N. MOORE, president, and BRADLEY STOUGHTON, secretary, of the American Institute of Mining Engineers, are making a tour of the West. They were the guests of the San Francisco section at a dinner and meeting on May 7.

Obituary

A. M. DAY, metallurgist at the International smelter at Tootle, Utah, died in Salt Lake City, May 2. He was born at Minneapolis, May 9, 1865. At one time he was superintendent of the Butte & Boston smelters at Butte, and also was for some time superintendent of the Yampa smelter.

GEORGE E. AMES died in San Francisco on May 11, at the age of 78 years. Mr. Ames was identified with the industrial development of San Francisco to a large degree, having been for many years in charge of the mining machinery department of the Union Iron Works. Many of the largest installations of milling, hoisting, and pumping-machinery in California, Nevada, and Montana were made under his supervision. In 1898 he resigned his position with the Union Iron Works to become chief engineer for the Anaconda Copper Mining Company on the solicitation of the late Marcus Daly. Following this engagement, he became Pacific Coast representative for the Allis-Chalmers Company, and later, consulting engineer for the Mascot Copper Company, afterward retiring to private life.

THE METAL MARKET

METAL PRICES

San Francisco, May 15

Antimony, cents per pound	23
Electrolytic copper, cents per pound	37
Pig lead, cents per pound	9.75-10.75
Platinum, soft and hard metal, per ounce	\$105-111
Quicksilver, per flask of 75 lb.	\$106
Spelter, cents per pound	12
Tin, cents per pound	65
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, May 15

Antimony, 50% metal, per unit	\$1.65
Chrome, 40% and over, f.o.b. cars California, cents per unit	50-55
Magnetite, crude, per ton	\$8.00-12.00
Tungsten, 60% WO ₃ , per unit	20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 45% (under 35% metal not desired), cents, unit	36-38

On this page in the issue of May 5 the content of merchantable manganese ore was stated in terms of MnO₂. This was an inadvertence, and occurred only in that one issue. Settlement for manganese ore is always made on the basis of the percentage of the metal contained, and not on the amount of di-oxide.

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

	Per unit
Above 49% metallic manganese	\$1.00
46 to 49% metallic manganese	0.98
43 to 46% metallic manganese	0.95
40 to 43% metallic manganese	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

Tungsten: Foreign business that was placed last week has helped to eliminate quite a tonnage of ore, again reducing the Eastern stock to an absolute minimum. No high-grade ore of any kind is to be had in quantities. Shipments from the West are delayed an account of difficulties in securing railroad cars, and though quite a number of manufacturers have contracted for ore at comparatively low prices, they are now forced to come into the open market and this has accentuated the position to such an extent that high-grade ore has been paid for at the new schedule prices.

EASTERN METAL MARKET

(By wire from New York)

May 15.—Copper is quiet but firmer at 32c. Lead is strong and scarce at 10.50c. Spelter is dull and steady at 9.37c. Platinum is quoted at \$105 to \$110.

The weekly circular letter of Samuel Montagu & Co. of London, of April 19, says: On April 5 the quotation receded to 36½d., and remained either at that figure, or 1/16 lower until yesterday, when a change came over the market in sharp contrast to the apathy of the preceding fortnight. Supplies of silver for some time have been scanty—a fact of little mo-

ment so long as demand kept small and fitful. Recently some China purchases, covering bear sales or otherwise, set in and the market was not broad enough to fill the demand.

It is understood that the United States government made further purchases last week, and the paucity of offerings from that quarter encourages the idea that coinage requirements for the States are likely to be a factor of some importance. In these circumstances much expansion of American supplies, even at advancing prices, can hardly be expected.

Continued pressure to buy upon a starved market may possibly carry the quotation to a figure more tempting to speculative holders, the number and holding of which have assumed modest proportions; or to a level at which China sales of some magnitude will become profitable.

The Indian currency return for April 15, as given below in lacs of rupees, shows a reduction of 62 lacs in the holding of silver, although the total of the note issue has increased by 37 lacs.

	Apr. 7	Apr. 15
Notes in circulation	8410	8447
Reserve in silver coin and bullion	1736	1674
Gold coin and bullion in India	1158	1219
Gold in England	667	592

The stock in Bombay consists of 1700 bars, as compared with 1900 bars last week.

The stock in Shanghai on April 14, 1917, consisted of about 28,000,000 oz. in sycee and \$16,400,000, as compared with about 30,600,000 oz. in sycee and \$16,700,000 on March 31, 1917.

June	90.00	74.70	...	Dec.	123.00	80.00	...

Quicksilver has taken a drop of \$7 per flask, to \$106, since May 8, at which time it was \$113. There is no particular cause to assign for this lower price, as the market is normal.

TIN

Prices in New York, in cents per pound.

Date	1915	1916	1917		1915	1916	1917
Jan.	34.40	41.76	44.10	July	37.38	38.37	...
Feb.	37.23	42.60	51.47	Aug.	34.37	38.88	...
Mch.	48.78	50.50	54.27	Sept.	33.12	36.06	...
Apr.	48.25	51.49	55.63	Oct.	33.00	41.10	...
May	39.28	49.10	...	Nov.	39.50	44.12	...
June	40.26	42.07	...	Dec.	38.71	42.55	...

Tin is higher than in many years, the prices mounting from day to day. On May 10 the price in New York was 64c. per pound.

Platinum is quoted at \$105 for soft unalloyed metal and \$110 for the hard natural platinum-iridium alloy.

Eastern Metal Market

New York, May 9.

Nearly all the metals show a stronger tone, especially those which were weak and dull very recently. More clarity is felt, though nothing is known definitely, regarding the probable policy of the Government as to its purchases and the price, especially as manifested in the recent sale of spelter, which is discussed below.

Copper is firmer with a strong tone and more business is reported than in some time past.

Zinc is not active and sales are few, but the tone is steady and firm.

Lead is stronger and higher, almost with each day. Sales the past week have been of fair volume.

Tin continues to advance and sentiment is bullish as to the future.

Antimony is the only weak metal on the list, having declined decidedly.

The steel market continues its strong tone and prices do not stop their advances, especially pig-iron. The trade is putting forth every effort to meet Government requirements as fast as they develop. Reports from Washington, that an outlay of \$1,000,000,000 is contemplated for ships, is termed hysterical and the suggestion that the products of every steel-mill in the country be diverted to Government uses is not taken seriously in well-informed circles.

COPPER

A more cheerful tone pervades the market on the more general conviction, based on fairly reliable sources of information, that the large purchases probably to be made by the United States and its Allies will not go at 16½c., but at a price nearer the market. Some place it at 25 to 27c. per lb. and an estimate of the combined needs is put at 1,250,000,000 lb. This is regarded as high in some quarters. Deducting this estimate from the probable output of this country for 1917, of 2,300,000,000 lb., only 550,000,000 lb. is left for ordinary domestic use, after the Allies' purchases early this year are taken into reckoning. At any rate, the market is stronger and demand is better. A steady business has been done lately. Sales of fairly large proportions were made last week for third-quarter delivery at about 29c., New York, which is the quotation for that position. Sales for June delivery have been made at 31c. These transactions are believed to have been confined to a few large consumers. The market as a whole is more cheerful with the bogey of a two-priced market removed, probably as an unsettling factor. The London quotation for spot electrolytic yesterday was £142, unchanged from last week. The quotation in New York, yesterday, for both Lake and electrolytic for spot delivery was 32 cents.

LEAD

Lead grows scarcer and the market stronger almost daily. Many large producers have withdrawn from the market pending the Government's decision regarding its actual wants and the price it will pay. It is reported that 2500 tons was sold during the last week to the Government for May-June delivery, but the price is a secret. This is regarded as relatively inconsequential as compared with the ultimate needs which will probably be large from July 1. The American Smelting & Refining Co. advanced its price ½c. per lb. to 9.50c., New York, on May 2, but with no immediate effect on the market. Sales have been made in the week at all prices, 9.50c., New York, 9.75c. for June shipment with May shipment from St. Louis at 10.50c. Yesterday June, delivered New York, went at 10.50c., with prompt shipment from the West at 10.40c. The quotation yesterday for early shipment was 10.45c., New York.

ZINC

A bullish factor, but one of little driving force just at present, has made its appearance in the official announcement of prices for metal to be furnished the Government. The zinc committee of the Council of National Defense has come out with a statement that for grade A spelter 11½c. per lb.; for grade B, 11c. per lb., and for grade C, 9c. per lb., all delivered, will be the ruling price, with the latter one protected against a decline. The significant fact is that the 9c. price is so near the market, that it puts to sleep the rumors of much lower official prices, which have been so disturbing. At these prices 25,000,000 lb. have been contracted for; but the Government purchases will be increased later. Business at present is very quiet and sales are few. Some buying is reported this week at 9.12½ to 9.25c., St. Louis, or 9.37½ to 9.50c., New York, which is regarded as the quotation, but the demand is small. The July price is pegged at 9c. by some.

ANTIMONY

The market has experienced a sudden decline. From a quotation of 32 to 32.50c. a week ago for prompt Chinese and Japanese grades, the metal was obtainable yesterday at 24 to 26c. The cause is the unexpected offering of two lots of overland shipment which met a dull market. It was not due to the fact that "shrapnel had gone out of style," as one dealer put it.

ALUMINUM

There is no change. Russia is buying large quantities of scrap-metal and absorbing anything that is pure enough, whether virgin metal or not. The quotation for No. 1 virgin aluminum is 59 to 61c. for early delivery, New York.

TIN

The market has developed a very strong tone with prices advancing almost daily. From a price of 58.25c., New York, on May 2, the quotation has risen to 58.50c., on May 4, to 59c. on May 7, and to 59.37½c. yesterday. In the past week sales of about 800 tons have been reported, a large part futures, but now sellers are more disinclined to sell despite a good demand. The first four days of the month the market was dull, though on May 3 there was a little activity with sales of 200 tons, mostly futures. On May 4 less than 100 tons was purchased. The best demand in a long time developed on Monday, May 7, when 250 to 300 tons was sold, but probably by only a few sellers. At present very little spot metal is available. More business could be done were sellers willing to part with their supplies. The dominating factor in the market is ships enough to bring the metal to this country. Without doubt mutually satisfactory arrangements will be entered into between this country and Great Britain to insure permits to ship enough metal to supply our needs. Arrivals for May to the 8th were 1000 tons, with the quantity afloat at 425 tons. The London quotation for spot Straits was £232 12s.6d., an advance of over £2 above last week.

ORES

TUNGSTEN. High-grade ore is reported scarce, due partly to sales in the past week of quantities, pending a week ago, for foreign consumption. Not much ore is reported sold at the new schedule of \$20 for 60% concentrate, though fair quantities have gone at \$17 to \$19 per unit, New York. Ferrotungsten is quoted at \$2 to \$2.15 per lb. of contained tungsten and there is good foreign demand from Italy and France for this and the ore.

MOLYBDENUM. The market is very quiet and dull, with the last quotation on molybdenite at \$2 per lb. of MoS₂.

ANTIMONY. There is no change since the report a week ago with the market lifeless.

Company Reports

PITTSBURG-DOLORES MINING CO.

Following is a resumé of operating expenses at Rockland, Nevada, for the period ended November 30, 1916.

Total time, 18 months from the starting of operations.

TONNAGES AND VALUES

	Per ton	Total value
23,326 tons mine rock	\$9.26	\$215,972.91
2,052 tons old dumps	4.00	8,208.00
337.17 tons tailing	2.82	951.10
1,097.48 tons tailing	2.75	3,021.96
456 tons tailing	4.86	2,215.69

Total\$230,369.66

The first two lots of tailing listed were from the old leaching-plant, and the last lot was from the old stamp-mill dump. Most of the old dumps were washed away by heavy rains during the last twenty years and the amount treated was only what had remained.

When the mine was sampled the average value of the mine-ore was calculated at \$9.40 per ton. It will be noticed that the ore produced averaged \$9.26 per ton or 14c. less than the estimated value. The mine costs were as follows:

	Per ton
Cost of mining	\$1.93
Cost of development	0.92
Miscellaneous	0.42
	<hr/> \$3.27
Tramming to mill	0.23
	<hr/> \$3.50

The tram is 1800 ft. long from the mouth of the tunnel to the mill.

During the period a total of 2900 ft. of raising was done at an average cost of \$3.16 per ft., and 2150 ft. of driving at a cost of \$4.62 per ft. The amount of driving was low as compared to raising, as the adits had been extended for long distances without raising between levels during the period of re-opening the old workings.

There were 26,609.06 tons of tailing discharged of a total value per ton of \$0.814. Extraction was 90.4%. The average cost of milling was \$2.75, but the costs were reduced from \$3.20 during the first six months, to \$2.28 during the last six months, notwithstanding continual increase in the price of supplies. This was brought about by mechanical improvements and metallurgical saving. It was also caused by the increase in the ratio of gold to silver in the ore which permitted a better extraction and also materially decreased the period of treatment. The bullion is now worth \$3.52 per oz. In January 1916 it was \$2.15 per oz. Only a small portion of the increase is caused by the present value of silver.

The average tons milled per day was 49. This was increased to 60 tons during last year. Assaying, office, and general expenses averaged 73c. per ton; \$18,748.95 was spent for construction.

Supplies increased in cost from 12%, for some minor items, to as high as 220% during the period. The increase is estimated at 68c. per ton for the period over the prices that prevailed when operations were started in the summer of 1915. There were \$6430 worth of supplies on hand November 30, 1916.

Owing to the lack of sufficient water in the district with which the treatment of a larger tonnage would be possible, the installation of a filter is recommended. At present two sets of rolls are used and the treatment of a larger tonnage with satisfactory results being impossible with these, the purchase

of a ball-mill to replace the rolls, screens, and elevator is also recommended.

It is estimated that a saving of \$1200 per month can be made on the basis of 80 tons milled per day. Development in the mine has been limited to the old workings which were partly re-opened.

In the winze below the lowest adit some new work has opened up a new ore-shoot for 250 ft., and an average value of \$12 per ton. Another long ore-shoot, averaging \$8 per ton, was opened up on the 2nd level and the quartz in this has been found very satisfactory for tube-mill pebbles.

The location of the mine is 27 miles south of Yerington, Nevada, in Mineral county.

E. J. Schrader is manager, J. B. Perry, is mine superintendent, and C. R. Olson, mill superintendent.

TOUGH-OAKES GOLD MINES, LIMITED

The annual report of the Tough-Oakes Gold Mines, Limited, for the year ended December 31, 1916, is as follows:

Total operating expenses\$ 375,774.53

Operating profit\$ 331,340.23

There are seven veins on the property on which little work has been done, and profiting by the experience gained during the past four years operations there is a reason for the belief that many new orebodies will be opened up after ample electric power is available for the full operation of the mine.

EDITORIAL

T. A. RICKARD, Editor

THE ALUMNI of the College of Mining of the University of California gathered at a banquet at the University Club in San Francisco on May 15, and effected a permanent organization, with Prof. A. C. Lawson as president and *ex officio* chairman of an executive committee that will continue to direct the activities of the association and arrange for future meetings. The alumni of the College of Mining now number 536, widely scattered throughout the world. It is difficult to keep trace of the graduates, and one object of the organization is to maintain a directory, partly to facilitate communication with engineers in answer to demands for the services of capable men. The secretary of the association is Mr. L. C. Uren.

MAGMATIC segregation is again to the fore in this issue, a general critical review of the subject being presented by Dr. Joseph T. Singewald, Jr., of Johns Hopkins University. He points out that the theories of the French school of economic geologists have received fresh confirmation by the studies recently made by Dr. C. F. Tolman, Jr., and Prof. Austin F. Rogers, of Stanford University. The evidence that the ore-minerals replace the silicates without forming metallic silicates, and that mineralizers were active in the formation of ore deposits of the character known as magmatic segregations, not only has been sustained by Tolman and Rogers, thus confirming De Launay, but is further corroborated by independent investigations made by Dr. Singewald upon a large number of titaniferous iron-ore deposits in the United States and elsewhere.

TAXATION of mining claims has commonly been assumed not to be permissible until the title had passed from the United States to an individual. This opinion is so widespread, and the failure to assess unpatented claims for purposes of taxation has been so nearly universal, as to give the sanction of custom to such exemption. Nevertheless the laws of California and of some other Western States have taken account of the possibility of deriving revenue from this source, and the possessory right of the locator is made amenable to a tax-demand. Cases have been decided by the Supreme Courts of the United States and of the State of California, holding that the possessory interest in public mineral lands acquired by location is subject to taxation by the State and its municipal subdivisions as real property. Only this possessory interest can be sold under a tax-sale, and the purchaser must perform the annual labor, otherwise the ground is again open for location. The same ruling applies to quarries and to timber be-

longing to individuals or corporations on the lands of the United States.

CHILEAN exports of sodium nitrate to the United States last year increased to about double the usual amount, reaching a total of 1,067,000 tons. Copper importations from Chile have a little more than doubled since 1913. It is noteworthy that our demand for Chilean iodine has been sharply emphasized, resulting in the importation of 1,044,000 pounds whereas the importations in normal periods seldom reached 300,000 pounds. The value of the iodine has risen likewise from \$1.34 to \$2.34 per pound, while the price of sodium nitrate has remained stationary, the prices in 1913 and 1916 respectively being \$33 and \$29.10 per ton. It is now announced that the United States government has arranged for the importation of \$10,000,000 worth of Chilean nitrate, and deposits of large extent in the province of Tarapacá have been acquired by Du Pont de Nemours & Company, which indicates that this great powder-making corporation fails to see possibilities of speedily supplying our needs for fixed nitrogen by the available electric processes and by an increase in the output of ammonia from by-product coking. At the same time important research-work by the Semet-Solvay Company on the oxidation of ammonia to nitric acid has resulted in setting apart its plant exclusively for Government service.

DISCUSSION this week is enriched by an account of work performed at Broken Hill, Australia, by Mr. W. E. Simpson, from which the conclusion was reached that flotation by the Potter process was dependent in part upon the formation of gelatinous silica adhering to the minerals of metallic lustre and forming them into aggregates by coagulation. The suggestion that the presence of flourspar was also essential in this case through the evolution of hydrofluoric acid in the reaction between that mineral and the sulphuric acid, thus producing in the pulp a reagent that would liberate silica in colloidal form, is another point of interest. Mr. W. Tovote contributes an important note on the catalytic effect of native copper in promoting the reduction of more copper from sulphate solutions, building up crystal aggregates of the metal. He also adduces reasons for suspecting that chalcantite may be altered into native copper, pseudomorphic after that mineral, in the presence of reducing agents in shale. Mr. F. H. Mason cites another example of large concentrations of nitrogen in rocks, and Mr. Fred T. Greene announces a precedent established in the case of one railroad for accepting an engineer's mine-samples as baggage.

Tin and Glass

Tin has given the Government considerable uneasiness. The price has risen from 55 to 65 cents per pound within the last three weeks. Insufficiency of the metal to meet recent demands is probably reflected with accuracy by these quotations. The shortage may be due in part to the uncertainties and difficulties of transportation. Some incline to the belief that the trouble is more fundamental, and intimate that an actual diminution is noted in the tin output from the Far East. Whatever the explanation, tin-stocks are low in comparison with apparent needs, and the Department of Agriculture has seen fit to advise the canners to desist from packing imperishable foods, such as peas, beans, and hominy, in tin-plate containers. Some lack of proper organization was thus disclosed. It turned out that the alarm over the scarcity of tin was based upon reports which the manufacturers of cans had sent to the Department giving estimates of the needs for putting up this season's crops, according to requisitions received from packers throughout the country. At this point official action was taken to conserve the supply of tin-plate, and the canners replied that the only fair procedure would be to make the restrictions obligatory upon all packers, otherwise compliance on the part of some would merely operate to benefit those competitors who might disregard the request made by the Secretary of Agriculture. It is now stated by the leading manufacturers of tin cans that the original estimates of the season's needs were too high; that many packers, fearing a *pro rata* reduction of the allowance of containers, had asked for three to four times as many cans as they actually expected to use, and in consequence the American Can Company has just notified its customers that they can furnish all that may be legitimately needed. If this be the case, there should be a sympathetic response by a slump in the tin market. It must not be overlooked, however, that Eastern packers have taken the reported shortage of tin-plate seriously, and the demand for glass jars has become so great that the glass-makers are six months behind on their orders, with no prospect of catching up. It would be possible, however, to quickly revive the manufacture of the old-fashioned green bottle-glass, which can be made cheaply and without the use of the alkalis that limit the potential production of glass so seriously at the present time. We believe this has already been suggested to the Department of Commerce. The bottle-glass of fifty years or more ago was made chiefly from basaltic rock of suitable composition. In France a rock containing about 45% silica, 16 alumina, 20 ferrous oxide, 9 lime, and 3 to 5 soda, was extensively used for this purpose. Basalts were also employed in England and at a few of the older plants in the United States. Common sea-sand likewise has been found suitable, adding lime when the amount present from comminuted shells is insufficient. Such sands also contain important amounts of soda from the salt left in them by evaporation, which better adapts them to fusion for glass manufacture. If the tin shortage should prove to

be real it is evident that means are at hand for supplying the lack with food containers of cheap glass. Small plants for the manufacture of jars from such material could be quickly established in many localities.

The Pyrite Problem

Sulphur is becoming daily a matter of deeper concern. It has been pointed out by Mr. Charles G. Wilson that the Union Sulphur Company in Louisiana, and the Freeport Sulphur Company in Texas cannot increase their output with sufficient rapidity to afford a supply of brimstone to take the place of the pyrite that would be required to produce sufficient sulphuric acid for fertilizer purposes within the time necessary to enable the manufacturers to meet the fertilizer needs for the fall crop of the present year. As a result of the existing situation, there has been abnormal activity in the investigation of sulphur deposits, which is justified in so far as such deposits can be made available for immediate exploitation. Deposits in Nevada and in Inyo county, California, are said to be promising, and large deposits of relatively low-grade but easily accessible sulphur are known to exist in western Texas, which are already being operated on a small scale. The methods of extraction from the superficial deposits in Texas so far have proved less efficient than might be desired, but it is largely a matter of technical detail to increase the degree of extraction. Under the present sharp accentuation of the demand, it would seem that these are as quickly available as any other deposits in the country. In the next place it should be pointed out that over a million tons, or 75%, of the total pyrite used in the United States for acid-making, comes from Spain, which supply has been entirely cut off. To keep up the production of acid it is necessary to install sulphur-burners in plants which are already equipped with pyrite-burners, which is a serious drawback. It would seem desirable that the case be met by some governmental provision whereby such highly pyritic ores and concentrates as contain considerable amounts of valuable metals in addition to copper, commonly known as complex ores, which would bear transportation to acid-plants, might be utilized to meet the emergency. Methods have already been worked out in sufficient detail to admit of the economic treatment of the cinder for the extraction of the larger part of the contained metals, and it would be appropriate that the Government should provide means that would permit of proper payment to shippers for the metalliferous content in these ores, even though the cinder should have to be stored for a period while preparations could be made for its further treatment reasonably near the point of roasting. The co-operation of the smelters and of ore-buyers in the West should be able to offer promptly to the sulphuric-acid plants a substitute for the Spanish pyrite. Some slight modification might have to be made in the pyrite-burners, but these are chiefly in the nature of means to prevent loss of heat by radiation, which present no insuperable difficulty.

Sampling Large Low-Grade Orebodies

Our readers will have noticed that in the interviews with Messrs. J. H. Mackenzie, D. C. Jackling, and H. C. Perkins we asked each of these engineers for their opinion concerning the practicability of sampling accurately such large low-grade orebodies as are being exploited in southeastern Alaska. The word 'erratic' might be added to the description of such orebodies, but this additional adjective is hardly necessary because the idea of irregularity is implicit: all large masses of gold ore are characterized by an irregular distribution of the precious metal, because so small a volume of gold is needed to change a ton of 'rock' into 'ore' that uniformity or homogeneity is out of the question. It will have been noted that not one of the experienced engineers whom we sounded on the subject expressed any faith in the efficacy of the moil and hammer as a means for sampling a mass of several hundred thousand tons of \$2 gold ore. Mr. Mackenzie advocated the milling of thousands of tons from different parts of the mine, and stated that the estimated average on which the Alaska Juneau enterprise is based was obtained by milling 50,000 tons broken across the orebody, supplemented by the information available from previous operations in the course of which 430,000 tons more had been milled. Even such large-scale sampling, he said, "is only an approximation, but it is as close as we can afford to go." Mr. Jackling could point with pride to the sampling, by means of churn-drills and also by mining, supplemented by mill-tests, on which the success of the Utah Copper was predicated; he also referred to the sampling of the Alaska Gastineau mine, which adjoins the Juneau, and explained how the results of sampling in this case had proved deceptive. The 375,000 tons milled by the previous owners of the property had been regarded as an average sample and the estimate based thereon had been confirmed by using a pilot-mill to crush large tonnages from different parts of the mine. Yet, when the big mill, having a capacity of 12,000 tons per day, started to work it was soon found that the yield per ton was \$1.25 instead of \$1.75 per ton, although both the estimates of cost and of recovery were more than substantiated. As Mr. Jackling says, it is easy to sample the disseminated copper deposits by drilling, and to do so both cheaply and accurately, because the orebodies lie flat and the copper is distributed with some degree of uniformity, but the large lodes of gold-bearing quartz standing at a high angle "cannot be tested," he says, "within the limits of reasonable expense for development, and with any satisfactory degree of accuracy." He also said that his experience at Juneau "indicates that sampling from development almost invariably shows results higher than they should be." Turning next to that sagacious veteran, Mr. H. C. Perkins, we find that he is much of the same mind. He did very little ordinary sampling before he advised the purchase of the Oriental Consolidated mines; he was furnished with trustworthy records of the yield from a number of small workings and from them he calculated

the yield of gold per square foot of vein. This figure he used as his chief guide, having ascertained the cost of working. We have quoted the testimony of these three experienced engineers because we regard it as the equal of a whole text-book on the subject. The question is one that we would like to see discussed thoroughly by competent engineers. One of them, Mr. Howard D. Smith, criticized our comment on Mr. Mackenzie's remarks in the issue of March 3, and we would like others to do so also. In order to give further scope for an intelligent ventilation of the subject, we re-publish an excellent article on 'Sampling an Erratic Orebody,' from *The Mining Magazine* of September 15. This article, by Mr. L. A. Parsons, is likely to have escaped the notice of many American engineers, and it is one that we are glad to place on record in our own pages, so that it may form part of the evidence in the case. It was prompted by an earlier article by Mr. Morton Webber, whom we also invite to return to the attack. Mr. Parsons, it will be seen, supports Mr. Howard Smith's contention and both these younger (but far from inexperienced) men hold views opposed to those quoted in the earlier part of this discussion. Is a mill-test more reliable than a number of moil-samples? Is not a mill-test after all merely one large sample and does not the doubt always arise whether it is thoroughly representative? Is the crushing of a large tonnage from one part of the mine much more than a big grab-sample—the type of the fortuitous—and are a number of such big mill-tests any more than a series of similar grab-samples? We hope that our readers will ponder these questions and send us a reply. Broadly speaking, sampling is based on the doctrine of averages; the larger the number of samples the more trustworthy the final result, provided each sample is representative of the portion of the lode from which it came. The idea that a mill-test is more reliable than a thousand moil-samples pre-supposes that the mill-test is more fairly representative than the numerous smaller samples. Here two axioms may be interjected. The first is that the ore milled by the owner of a mine before he sells it is likely to be of more than average grade, and the better the miner in charge the more likely is his output to be of super-grade. For instance, the late John R. Mitchell, the former superintendent of the Alaska Perseverance, was a fine miner and just the man whom we should expect to select the best part of the lode for his stopes. All good mining is selective in a large way; it involves choosing those portions of the orebody that are likely to be profitable and then rejecting, as far as is economical, the waste inevitably broken with the ore. The second axiom is that any method of sampling, even on a big scale, by mining, but more particularly on a small scale, by moiling, yields a cleaner product than is obtained in the course of normal operations underground. Any sampling must be subjected to a discount in order to bring it to the basis of stoping in the usual way. Those who have sampled many mines know that the discrepancy between the early reports of competent engineers and the subsequent history of a mine does not come so often

from an incorrect estimate of the amount of metal produced as from a difference of ratio between tonnage and yield. The tonnage is greater and the yield per ton is less, as a rule, because the ore is not broken as cleanly as in sampling, and because a lowering of cost by efficient management leads progressively to the breaking of lower-grade ore. After all, the crux of the problem lies in the weighting of the data after they have been determined. One man takes a dozen samples, another a thousand, a third crushes 100,000 tons of ore, and in each case the evidence obtained is only crude material for intelligent ratiocination, beginning with correct inferences and ending in just conclusions. Any one of the three methods, plus a correct diagnosis of the ore occurrence, plus a dissection of the mine-records, plus a knowledge of human nature, plus technical experience, may suffice to furnish the information leading to a true estimate of the capabilities of a given mine, and any one of them by itself may prove fallacious. The subject is one of perennial interest, and the importance of it has received such emphasis lately that we hope to see it discussed thoroughly and carefully in the pages of this paper.

Our Restrictive Alcohol Laws

Alcohol has become an important problem in our preparations for effective warfare. In its industrial applications alcohol is one of the best friends that man possesses. The pages of a single issue of this paper would not suffice to enumerate the technical uses of this important substance. Considered with direct reference to the needs developed by the intense military activity of the hour, among which may be mentioned, aside from explosives, the demand for the manufacture of medicinal tinctures which will be larger than ever before, as well as the requirements for the manufacture of enormous quantities of ether, in which alcohol is an absolute necessity, it becomes apparent that early legislative action is desirable. It has been pointed out by Mr. Richard H. Edmonds that a war prohibition-measure would save enough grain to provide a loaf of bread per diem for 11,000,000 men. This is one way of looking at the problem, and a useful way. It indicates furthermore that the use of alcohol in beverages reduces the amount available for necessary purposes in manufactures, including the provision of medical comforts. But this is not all; the kitchen waste, part of which is unavoidable, constitutes to an important extent, an available source of alcohol, but we are not organized for utilizing this material. The remedy lies with Congress. Some years ago a number of patriotic citizens in this country undertook a denatured-alcohol propaganda. An association was formed in New York, and thousands of men throughout the country contributed to the support of the organization, the purpose of which was to educate the people to the possibilities of denatured-alcohol to be used partly as a substitute for pure alcohol in a large number of industries where the adulterant produces no detrimental effect, and chiefly as a source of cheap heat, light, and power, in small plants. Had such a wise measure as the denatured alcohol asso-

ciation proposed been passed by Congress, the development of the country would have been promoted in various ways, and agriculture itself would have experienced a stimulus which would have tended to cheapen the cost of food supplies as well, since the rotation of crops would have been necessary, and the net result would have been to bring larger areas under cultivation. When the agitation had reached a point where it was inevitable that some action would be taken, the Standard Oil Company, realizing that this competition would lessen its ability to control the gasoline-market, succeeded in having a bill introduced as a substitute for the one that was intended to provide cheap alcohol for the public, and this substitute-bill placed such restrictions upon the manufacture of denatured alcohol as to prevent production under conditions that would admit of small local associations entering into the business. It is time that Congress should reconsider this question, and put on the statute-books a denatured-alcohol act that will permit of manufacturing this commodity under economical conditions. Dr. Allen Rogers has recently insisted that, "instead of making alcohol for drinks, we should make it for the manufacture of explosives, for ether, for medicinal purposes, for fuel, for dyes, shellacs, and for every use to which it can be put in this supreme moment when all things must be turned to the Nation's greatest good." It is certainly suicidal to permit the sale of alcohol as a beverage at a time when it is urgently needed for the safety of the Nation in war, and it will be hard for Congress to excuse itself for having failed to utilize the waste materials of the country in the manufacture of denatured alcohol, when all the world knows that the present laws are restrictive in their operation and intent, and were so drawn for the benefit of a few wealthy monopolists. At the same time synthetic alcohol has been made a possibility by a process already established on a working basis in Switzerland. This involves first of all the manufacture of calcium carbide in the electric furnace. Acetylene is generated from the carbide in the ordinary way by water, and then, under the influence of a catalyzer, hydrogen is added to the molecule, producing ethylene. That in turn is dissolved in sulphuric acid, and saponified by boiling with water, when it yields alcohol with regeneration of sulphuric acid. Thus it is possible to utilize the waste water-power of the Pacific Coast and of the South Atlantic States in the manufacture of calcium carbide to be directed to the production of alcohol, but such enterprises are hampered by the enormous tax of \$2 per gallon on spirits. The excise tax fails to restrict the use of alcohol in beverages, while it embarrasses its legitimate industrial application. Prevention of the improper consumption of alcohol can be effected by suitable prohibition measures, coupled with provisions that would limit its manufacture, sale, and technical use, under the control of persons required to give bond in appropriate sums. Development and control of the alcohol industry should be constituted a public trust, but should be no more complicated by obstructionist legislation than the conduct of banking, which also necessitates reliance upon an army of trustworthy men.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Potter Process at Broken Hill, Australia

The Editor:

Sir—In response to an invitation in the MINING AND SCIENTIFIC PRESS, of March 17, I wish to direct attention to two statements in the discussion of the Potter process which are not strictly in accordance with results obtained by extensive investigation and experiment under my superintendence at the works of the Zinc Corporation at Broken Hill, Australia, now nearly a dozen years ago. The “derivatives capable of replacing oil” in the Broken Hill tailings are not “shrubs and other organic substances” but the common minerals fluor spar and quartz which react with the hot sulphuric acid, to form gelatinous silica, a substance possessing certain physical properties, including that of selective adhesion to lustrous bodies, similar to those of thick oils or grease. This is a matter which, although extremely interesting, has not yet, so far as I am aware, been recorded in the literature of flotation work. The only published reference to it seems to be that contained in a short letter which I wrote in 1910 for the *London Mining Magazine*. Certain investigators, as for example, O. C. Ralston and Glenn L. Allen (M. & S. P., Jan. 1, 1916) have, however, observed, when experimenting with the Potter process on a laboratory scale, that “a great deal of mineral is often partly lifted but never reaches the surface. Consequently extractions are low.” This would indicate that the materials then under examination were lacking in these very “derivatives capable of replacing oil” otherwise the mineral would reach the surface and tend to persistently stay there. By blending the component minerals in rotation so as to gradually produce an artificial mixture with similar composition to that of the Broken Hill material, and noting the results obtained on immersing in hot sulphuric acid, A. J. F. De Bavay has shown that the absence of fluor spar would render the Potter process impracticable. The mineral would tend to rise to the surface, but would not remain there a sufficient length of time to permit of its transference to a suitable receptacle for collection as a valuable product. While on this subject, I may also correct a statement of C. T. Durell (M. & S. P., Feb. 19, 1916) who, in comparing the value of representative concentrates produced at the various Broken Hill flotation plants, reported that the difference in the grade is obtained “by reason of mechanical refinements and not the difference in process.” My own researches have proved that the particles of sulphide recovered by the Potter process and also by the Delprat modification, are smeared with colloidal silica

to the extent of about 5% of the actual weight of the concentrate produced, and that the tenacity of the adhesion is so great that separation is not possible in the wet state by mechanical means. If heat, however, be applied to the concentrate, its greasy shining appearance quickly disappears, the silica crystallizes, and its separation is easily effected on Wilfley tables or with magnetic machines.

The second inaccuracy is the inference that the all-important flotation agents in the process are the bubbles of carbonic acid which “by attaching themselves to particles of mineral buoy them to the surface.” In a series of tests which I conducted in 1906 on a gradually increasing scale from that of 100 grammes in the laboratory to that of 1000 tons in the full-size plant, I was able to prove that the influence of carbonic acid is chiefly that of an auxiliary flotative agent, operating by becoming mechanically entangled in the clotted masses of the silica-smeared sulphide particles, and that, in reality, the fundamental buoying factor in the Potter, as in all other flotation processes, is air. The Broken Hill tailing, to which the Potter was the first flotation process applied, is composed of the sulphides zinc blende, argentite, and galena, and of rhodonite, quartz, calcite, and fluor spar, as gangue. The pioneer plant was erected on the Block 14 mine for the purpose of recovering the valuable sulphides of zinc and silver from an accumulation of tailing derived from ore that had previously been finely crushed and treated on Wilfley tables for the extraction of lead. The results were highly profitable, another contributing factor to success being that the dumps selected for treatment contained material that had been carefully sized and washed free from slime and proved to be among the very richest in silver-content in the whole Broken Hill district. Usually when a suitable system of metallurgical treatment for an ore is being sought, consideration is given primarily to its chemical nature, but, with flotation work, most other factors possess a highly important bearing which the metallurgist, trained in the school of chemical reasoning, is likely to overlook. In this connection it is worthy of note that Charles V. Potter, the discoverer of the process to which he gave his name, was a pharmaceutical chemist, who, judging from correspondence that I personally had with him, knew little of general metallurgy and absolutely nothing of the principles governing the success of his own invention, and that A. J. F. De Bavay, Australia's brilliant investigator, was, by profession, originally a bacteriologist, trained at the Pasteur Institute in Paris. Incidentally, too, I may mention that in conducting the original work for the Zinc Corporation

in 1905-6, I found frequently that my own past experience in other branches of metallurgy, principally in cyanidation, was to a certain extent somewhat of a handicap. This was particularly the case when I installed a labor-saving device in the form of a conveyor-belt for receiving the zinc-bearing tailing from the lead-extraction mill, draining it of its associated water, and delivering it as feed into the hot sulphuric acid of the Potter appliances, all in one operation, thereby replacing the costly system then in vogue of trucking the wet tailing to a dump and, at a later date, shoveling it into cars and raising it to the receiving level of the flotation plant. From an economic point of view this alteration was a splendid success, but the metallurgical result was a worrying disappointment. Carbonic acid was liberated in abundance, but the sulphide particles refused to rise, and the extraction fell almost to zero. The solution had gone 'flat' and the froth, which previously had been so characteristic of the successful working of the process, had disappeared. So bad was the situation that flotation had to be suspended and a campaign of investigation started, a state of affairs not agreeable to the Zinc Corporation directors. Chemical analysis failed to indicate the cause of the trouble, and consequently the material as crushed was allowed to accumulate on the dump for later treatment. It was then noticed in laboratory tests that the extraction improved with the length of time that the material was allowed to remain on the dump. A resumption of operations on this self-same, partly dried material gave unexpectedly favorable results, the actual extraction being 92.5% of the zinc-content, yielding a concentrate assaying 46% zinc, this being a grade higher by 4 units than the best previous record. It must be remembered that this was in July 1906 when chemistry was the sole science of reference generally employed to explain metallurgical phenomena, and when practically nothing was known of the physical principles involved in flotation work. At this point, it dawned on me that aeration was essential, and further experiment confirmed that view. The culminating point was reached when I rigged up some make-shift appliances to test my conclusions on a 1000-ton scale.

Large galvanized iron tanks were rapidly erected, fitted with filter-bottoms as for cyanide work, and, as a temporary expedient, were filled in turn with the pulp from the mill by means of a hose. Drainage through the filter-bottoms was assisted by a vacuum created by a steam injector. When sufficiently drained, and consequently aerated, the interstitial spaces between the tailing-particles being filled with air instead of water as formerly, the content of each tank was discharged by shovel upon a conveyor-belt and fed direct to the Potter appliances. The results obtained caused excitement both locally and among the stockholders abroad, for not only was the extraction considerably higher than had been expected, but the grade of concentrate produced was of a quality then believed to be obtainable only by the use of oil.

To further demonstrate the possibilities of the Potter

process on suitable material I had a quantity of concentrate dried and treated on a magnetic separator and obtained a finished product assaying 51% zinc which, because of the associated iron in the mineral, is as high a grade as is possible to obtain. The waste products from the magnetic machine were white crystalline silica and galena. My researches with the Potter process showed that its fundamental buoying agent is air, that the 'collector' is colloidal silica which, in the gentle current of hot sulphuric acid, collects the air-enveloped sulphide-particles into clots, and that carbonic acid bubbles, by becoming entangled in these clots, help to bring them to the surface as a scum or froth.

W. E. SIMPSON.

Cobalt, Ontario, May 7.

Mine Samples as Baggage

The Editor:

Sir—Your issue of March 31 contains a letter from Horace Stanton on a subject which claimed my interest some time ago. I had a similar experience with a baggage-man at Seattle in 1913 and wrote to W. H. Merriman the Division Freight and Passenger Agent here in Butte as follows: "On my return to this country from a mine examination in British Columbia, I had with me a large leather sack, commonly known as a 'War Bag.' This sack is of a type in general use by mining engineers, constructed of sole-leather or some equally heavy leather, with handles at each end, and bound by a heavy trunk-strap. Up until this trip I have never had the question raised by the Northern Pacific Railway as to whether the sack was checkable or not. These sacks are used to carry digging-clothes, such things as are necessary to a mine examination, and the samples taken at each mine visited. It is necessary in a mining engineer's work that these samples should accompany him and reach his destination at the same time he himself does. This can be accomplished, usually, only by checking the sack as baggage. At your Seattle baggage-room, the baggage-master refused to check this bag, on the ground that the samples were not personal effects, and therefore were uncheckable. I was forced to send the bag by express, and I enclose the receipt for the same. It seems to me that these samples should be regarded as personal effects, for the simple reason that they are not a commercial commodity, and are of no market value. They are of no use to anyone, except the engineer who has taken them. They are a part of his outfit, and as such, are as necessary to the transaction of his business as the samples carried by a commercial traveler. In a sense they are representative of the value of what he has to offer to a market, in the same way that a traveler's samples are. Under the circumstances it seems to me that this bag should have been checked, and that I am entitled to a refund in the amount of the express, \$11.85, paid to the Northern Express Company."

Mr. Merriman took it up with the head-office at St. Paul with the result that they took the same view re-

garding my samples as that expressed in my letter, and a proper refund was made. Later I wrote to Bradley Stoughton, hoping that the Institute could take some action which would require all the railroads to adopt the view of the Northern Pacific. Mr. Stoughton's reply is enclosed, but, so far as I know, no further steps were taken in the matter. Since 1913 I have had no trouble with the railroads in the North-west except the Grand Trunk-Pacific. In the South-west I find that the Santa Fe and the Arizona Eastern refuse to check such baggage.

FRED T. GREENE.

Butte, Montana, April 11.

(Copy of letter to Fred T. Greene.)

September 22, 1913.

Dear Mr. Greene:

I am very glad indeed to receive your letter of September 14, concerning the action of the railroads in refusing to carry bags containing samples for assay. It is just this sort of thing that we like to be informed of, as it seems to be an opportunity for the Institute to do good by co-operation on all sides. I only returned this morning from nearly two months absence at the Butte meeting, visiting the local sections, so I can only acknowledge your letter, but will write you more fully later. Again assuring you of our pleasure in having these matters brought to our attention, and with personal good wishes,

Faithfully yours,

BRADLEY STOUGHTON,
Secretary.

A Stalagmite of Native Copper

The Editor:

Sir—In the Butternut mine near Mayer, Arizona, was recently found a stalagmite of copper, capping the nut of a hanging rod in the shaft. The specimen is now in the possession of Maj. A. J. Pickerell, at Prescott. It is about 3 in. high by 1 in. diameter and weighs about one pound. The copper is crystallized throughout, and clusters of fairly well developed crystals branch laterally from the main column. From all I can learn the copper must have formed during the last 4 to 7 years. This occurrence strikes me as remarkable, not only on account of the rapidity of the precipitation and the beauty of the specimen, but also because apparently chemical reactions must have taken place that usually are not considered in the genesis of copper deposits, namely, the direct precipitation of native copper from copper sulphate solutions here with native copper acting as a catalytic. While the beginning of the precipitation is apparently due to the normal displacement of copper by iron in the sulphate solution, with simultaneous deposition of native copper, the further growth of the stalagmite cannot be explained in the same way, and I believe it possible that other reducing agents might accomplish the same process. There are, for instance, the remarkable seams of native copper and cuprite, the cuprite in this case being a result of the

direct oxidation from the native state, occurring in certain shales in Morenci. Waldemar Lindgren remarks on this peculiar occurrence, and explains it as a replacement of chalcocite, if I remember correctly. These seams are narrow, and show radiation, and are structurally almost identical to chalcantite seams found in the same locality. I was inclined to consider them as pseudomorphs of native copper and cuprite after chalcantite, and I believe now, more than ever, that this explanation might be correct.

W. TOVOTE.

Bisbee, Arizona, May 11.

Nitrogen in Metal Mines

The Editor:

Sir—Relative to the articles that have been appearing on this subject, an interesting occurrence is noted in 'A List of Canadian Mineral Occurrences,' by Robt. A. A. Johnston, of a bore-hole put down on Pender island, Strait of Georgia, B. C., from which natural gas composed of 94% nitrogen and 6% carbonic acid with a trace of oxygen was issuing at the rate of 100 cubic feet per minute. No account is given of the formation; perhaps Mr. Johnston can throw some light on this point.

If other conditions were favorable, such a gas would be useful for the manufacture of synthetic ammonia.

F. H. MASON.

San Diego, Cal., April 30.

ELECTRIC-STEEL production in the United States has progressed so rapidly, according to a statement by John A. Mathews in the Bulletin of the American Electrochemical Society, that the existing plants have a capacity eight times greater than the crucible-steel output, and one-eighth more than that of bessemer steel. The total production is 1,250,000 gross tons of ingots and castings, coming from over 100 plants in operation. Electric steel is chemically purer than any other, and sulphur especially is easily removed. Segregation of phosphorus or sulphur is not to be feared, and hence the percentage of 'cropping' is reduced, thus effecting economy. These steels, moreover, are freer from slag and non-metallic inclusions than bessemer and open-hearth steel. The use of the electric furnace admits of recovering good steel from low-grade scrap, and of producing a maximum yield of sound metal from a minimum of raw material. The chief drawback to the development of the industry is the policy of the Government, which prevents the economic utilization of water-power. In Norway hydroelectric power can be had for \$6 to \$12 per horse-power-year. In this country the average is above \$20.

TOTAL GOLD in general stock in the United States on May 1 was \$3,088,904,808. The U. S. Treasury held as an asset of the Government \$203,868,088 and the gold in circulation was estimated at \$667,338,062. An outward movement of gold is also noted, a shipment of \$3,250,000 from San Francisco to Japan having just been made.

Sampling an Erratic Orebody

By L. A. PARSONS

*In your issue of February last there appeared an interesting article by Mr. Morton Webber on 'Latent Errors in Mine-Sampling.' In this article Mr. Webber classifies the type of erratic ore occurrence, in which the valuable mineral occurs in bunches, under the general heading 'Mines where Sampling is no Use,' and recommends the mill-test as the only reliable method of valuing such mines. To quote: "The only method of reliable valuation in a deposit of this type would be based on authentic record of past yield, in combination with competently selected representative shipments of the remaining ore."

With this I cannot altogether agree. Authentic record of past yield is of the utmost value, but I believe that this is much better studied in combination with proper sampling than with mill tests. I do not refer to those tests made to determine metallurgical treatment, or to those made over an extended period of time to confirm sampling results, and which amount to operating the mine under option, but to the mill-tests designed to take the place of sampling because considered more reliable—'representative shipments.' These practically amount to large samples, and my contention is that they are no more justified in an erratic mine than in a uniform one; rather less so, if anything, for the chances of error are greater, and the safety resulting from averaging a large number of samples is needed. Before discussing this further, I shall describe briefly the methods used and results obtained at one mine of this type that I had the privilege of sampling and studying in great detail for a period of two years. This mine forms an excellent illustration of this type of deposit, and of some of the principles that affect the accuracy of the results when sampling by the ordinary hammer-and-moil method.

The formation at the mine in question consisted of highly metamorphosed sediments and igneous rocks, carrying irregularly scattered lenses of gold-bearing quartz ranging from almost microscopic size to several feet in thickness. These schists without quartz would assay from nil to about 3 dwt., averaging less than 1 dwt., and the quartz from nil to several hundred pennyweights. Frequently the gold was in coarse flakes, making most brilliant showings. The quartz stringers, in combination with the richer portion of the schists, formed erratic ore-zones separated by comparatively large zones of waste, and showed no consistency, taken either singly or in groups of any size. There was no habit or condition that could be discovered affecting the sudden changes from spectacular ore to practically barren waste. Mr. Webber mentions levels 30 ft. apart giving erratic results. I remember one cross-cut, sampled by a continuous

channel along each wall, of which, over a distance of 200 ft., one wall averaged one-third of the other. These walls were perhaps 5 ft. apart. The troublesome nature of the ore was evidenced wherever samples were used; in the assay-office, duplicates would not check at all unless ground to 200-mesh; in the mill, samples of battery pulp over a month would not check amalgam plus cyanide headings. The amount of underground development was hardly greater than would have been necessary to stope a uniform deposit of the same size, and very different from the network that Mr. Webber states to be necessary for deposits of this type. Levels about 80 ft. apart, and drifts and cross-cuts about 150 ft. and 75 ft., with of course local modifications for all of these, is not a large development proportion. In fact, per ton of ore blocked, it is small. According to my opinion these conditions formed as extreme an example of Mr. Webber's classification and as difficult a problem as one would be likely to run across. And yet this mine was sampled and ore blocked out, and is being sampled today. The results are of the utmost value, both to the men financing the property and to the management planning exploration and development work. It *had* to be sampled. There was no other method of working it intelligently.

The method of sampling did not differ in any essential from that in general use by a large number of engineers, so a brief description of this should suffice to make it clear. As neither the quartz stringers nor the ore zones had any definite trend, samples could have been taken in almost any direction. For ease in sampling all channels were cut horizontally about breast high along the sides of the drifts and cross-cuts. A distinction was made between drifts and cross-cuts according to their relations to the stopes, but structurally they were the same. Both sides were sampled, as so little was known about the deposit at first that all the information obtainable was needed. These channels were the usual kind cut with a hammer andmoil, and yielded about 1.5 lb. per ft. The rock surface was first cleaned with a scrubbing-brush, and the channel, about 3½ in. wide, outlined with chalk. The samples were caught in an ordinary iron meat-pan about 12 by 18 by 2 in. This was more easily cleaned than a candle-box or canvas, and made possible a more detailed examination of the sample as it was cut. In the low-grade or barren schist, samples were taken up to 60 in. long, but in ground which was apparently rich no sample was taken more than 30 in. long. This was in uniform rock. With every change in the character of the ground the sample was bagged and a new one started. In small quartz stringers this would frequently give samples not over 3 in. long. In such cases the size of the channel was always increased to make

*Reproduced from *The Mining Magazine* of September 1915.

the total weight of sample not less than 2 lb. Quartz containing the coarsest gold was not avoided in any way, but everything within the outline taken as mechanically as possible. Any adjustment necessary was made in the office afterward.

The question of high assays was of course always coming up. The first step in their treatment was re-sampling. All places yielding erratic assays were re-sampled in the bottom of the original channel. The decision as to whether an assay was erratic or not did not depend so much upon its tenor as upon that of its neighbors. An assay of 10 dwt. in one place might mean a re-sample and in another one of 50 dwt. be let go. The two or three assays of the same place thus obtained were averaged and the resultant tenor entered in the records with no reduction. At the times of calculating the ore-reserves, when studying the relation of each sample to all the others, it occasionally seemed advisable to cut down an assay to a tenor more consistent with the apparent structural importance of the rich spot yielding the sample. In addition to this, an arbitrary high figure of 500 dwt. was adopted, to which all assays above that figure were reduced. There were so few assays higher than 500 dwt. that it was thought they would affect the average out of proportion to the probabilities of their being duplicated in the interior of the blocks. These two causes combined affected a negligible proportion of the assays—probably less than one-tenth of 1%—and it is merely to show the methods of work that they are mentioned here.

In connection with the re-sampling an interesting fact was observed: the majority of times the re-sample gave a lower result than the original. I think the reason for this is clear. The occurrences of rich specimen ore were on the average so small that it was probable a large proportion of such an occurrence would be cut away by the offending sample. Similarly, I have no doubt that re-samples of the promising looking ground which had returned low assays would have given on the average higher results than the original. The averaging of the two assays thus introduced a slight factor of safety.

It will be evident from what I have said regarding the size of the rich zones that any attempt to mine them separately would have been absurd. The only feasible project was to take all within the mineralized zone. Therefore, in valuing ore blocked by the sampling results, the ground was considered as a low-grade mass, and no attempt was made to segregate tonnages for the small rich zones. This resulted in a method much the same as would have been used for a more uniform deposit. After the few adjustments of the high assays had been made as described above, the ground was divided into areas as indicated by the horizontal workings, and each area valued by dividing the total inch-pennyweights of the periphery, high and low alike, by the total sample-length in inches. The blocks between levels were valued by weighting the tenor at each level by the area blocked. Raises in general were used merely to prove continuity of ore, although occasionally their tenor was averaged

with that of the levels. The final result was adjusted according to knowledge of the mine. Bore-hole results were of great assistance in this, although used entirely for information as to continuity and not for obtaining tenor; and as mining progressed the samples from the development were supplemented by moil-samples from the stopes. The latter were averaged with the development samples when practicable.

The results of this method were highly gratifying. For a period of two years, the tenor of the total ore mined as indicated by moil-samples, when compared to amalgam plus cyanide headings for a quarter of a million tons milled, indicated a sampling factor of 112%. I regret that I am not at liberty to give figures in greater detail, but I think these will illustrate my point. It may be contended that these results indicate nothing, because the work was done by the staff, who brought their intimate knowledge of the mine to the final interpretation of the results. This was undoubtedly a factor, but it was a factor dependent upon experience and not upon any lessening of the difficulty of the work. Any independent engineer with sufficient experience could have arrived at the same results. In fact, in the early history of the mine, an examination was made by an independent engineer who predicted almost exactly what would occur.

The above example illustrates certain principles that I think can be applied in a greater or less degree when sampling any erratic deposit. Although it is an axiom in mine valuation that every mine must be judged on its merits, according to the experience of the examining engineer, and no hard and fast rules can be laid down, still I think these principles form a good foundation for working, and are certainly of more general application than considering sampling utterly unreliable and not using it for the data that it can give. I shall try to state these principles as I see them, omitting the actual manipulation of the sample, precautions against the increased danger of salting oneself, and details of that nature as being sufficiently taken up in the short description of actual practice above.

How to average high assays is apparently the question that bothers the majority of men most. There is a vast difference between the occasional high assay in ore of essentially uniform tenor, and the condition where the recurrence of very high erratic assays makes up almost the entire value of the ore. In the latter case I believe the result will in general be nearer the truth if high assays are reduced very sparingly, and then only for extremely good reason; assuming, of course, that there is sufficient development work to allow the law of averages to work. A high assay represents the tenor at a spot sampled. Whether that ore extends to the next development working or not is immaterial; the assumption is that it will be duplicated by other small patches within the blocks. Erratic and variable though the rich intersections may be over short distances or in workings close together, when taken over sufficient length of workings the average will represent, within the limits of error to be decided by the engineer, what the entire mass of

ore blocked out will yield. The theory is exactly the same as that which governs uniform deposits, but engineers seem to fear to apply it to the type under discussion. The high assays in the mine I have described were not sufficiently frequent to consider them the usual thing—in fact quite distressingly infrequent at times—and yet an attempt to cut them down by any of the well vouched for methods would have resulted in indicating on paper merely a large mass of waste. I am not at all sure, from the mine's subsequent history, that even the slightest reductions I described were justified. When sampling such a deposit, samples should be cut impartially through rich and poor alike, the mine studied structurally, and when the assays are in, all the information correlated before making up the averages. Then if for any reason some assays should be reduced, well and good; but an assay should not be reduced without knowing why it is done, merely on account of some vague idea that it is good practice and playing safe.

Two much discussed methods for increasing the accuracy of the results on such a deposit are decreasing the sampling interval and cutting the ore into small blocks. I do not believe that either of these is exactly the remedy. What is desired in sampling is to obtain sections of the orebody that are representative of its tenor as a whole. It is obvious that if the development openings are not thus representative, no amount of close sampling will increase the accuracy of the final result; it will merely increase the accuracy of the tenor assigned to those development workings. Therefore the sampling interval need only be small enough to give the tenor of the workings to a degree of accuracy consistent with their representation of the mine as a whole. Decreasing the intervals below this point adds nothing. As for cutting the ore into small blocks, this will increase the accuracy of the estimate for each block, and therefore for the entire developed portion of the mine; but is that exactly what we are after? In most cases the maximum amount of development that can be done is more or less a fixed quantity; compressor capacity, shaft or tunnel capacity, and cost limitations all contribute to this. The development that is used to cut already developed ore into smaller blocks is not exploring the mine for extension; and it is the results of this exploration that more than compensate the engineer for the lessened accuracy of each single block. To put it differently: the smaller the blocks, the more nearly accurate is the tenor assigned to the ore thus outlined; but if we grant that this ore is only a small portion of the whole, then the larger the blocks, that is, the more the development is spread out, the more representative of the whole this development will be. There must be enough samples for the law of averages to work, for the high assays to represent what will, on the average, be found in the interiors of the blocks. As shown above, obtaining this number by decreasing the sampling interval avails nothing; the samples must be from representative development. Therefore the accuracy of the result when sampling an erratic mine depends most upon the total amount of develop-

ment in the ore, not the amount per ton, and the blocks need not be smaller than would be required for mining.

The question of valuing by sampling a mine where the values are like 'plums in a pudding,' as it has been so aptly phrased, compared to the mine where values are evenly distributed, is not one of impossibility, but of relative accuracy. The error will be larger than with a uniform deposit, but as long as the probable limits of error are known, the results will often be as useful as if they were more accurate. Within these limits of error, by working according to the principles outlined above, ore can be blocked out as in the uniform deposit. However bad conditions may be, they will affect the mill test more than they will sampling. Certainly I know of no method of making a mill test on the mine I have described that would have yielded information at all comparable for accuracy with that obtained by sampling. Two years' actual production gave no indication of what the tenor of the mine as a whole would be; yet the current sampling indicated it after the mill had been running six months. It was over two years after a certain tenor had been predicted by sampling before the mill results began to conform to that tenor. The reason for this is perfectly obvious: the stoping was not done from representative places. *Representative*—that is the crucial point. Unless a man is a clairvoyant, there is no method of obtaining representative shipments. And if he could select the proper places, a few holes one way or the other by the machine men would entirely alter the tenor of the test. It comes right down to the old question of a few very large samples versus an enormous number of small ones—a question that has been many times discussed. Obviously, I am an advocate of small samples.

It seems to me that often such stress is laid upon great precision in mine sampling and valuation that sight is lost of larger issues that are more vital. Some of these have been outlined above, such as spending time and money on work whose sole object is to gain greater precision in the tenor that is assigned to the ore, rather than spending it on exploratory work that would give much needed information as to the future of the mine. And certainly this striving for great precision has no more serious consequences than when it prevents an engineer from giving any opinion as to the value of a mine, because its character is such that the results cannot be accurate within the limits of error he has assigned himself. The erratic mine is the most difficult problem the examining engineer has to face, but that does not alter the fact that it must, upon occasion, be faced. To reduce high assays sweepingly for no reason except custom, or to refuse to place any reliance upon sampling through an excess of conservatism, is to side-step the issue. The best opinion obtainable on the value of this type of mine is that honestly given by an experienced engineer without undue conservatism or optimism, after an adequate study of the mine structurally, a thorough sampling, and an analysis and correlation of the assay returns with the structural data obtained, and past yield if obtainable. To this opinion an engineer's clients are entitled.

VERBLINKING POWER-STATION ON THE VAAL RIVER

Mining Problems on the Rand

By H. FOSTER BAIN

A complete discussion of the various problems that confront the mining engineers and metallurgists of the Rand is far beyond my scope. The title of this article is intended rather to call attention to the fact that there are still unsolved problems on the Rand and that there are points in current practice regarding which a visitor may have doubts. It will do no harm to ventilate these questions. If the criticism be justified it may lead the able engineers and managers on the Rand to search for and perhaps to find a better way; if it can be shown to be unjustified it may still serve the useful purpose of calling out from some of our friends a clear statement of the reasons underlying the course adopted, and so result in contributions to technical literature of permanent value.

It is well at the beginning to point out the peculiar conditions under which a Rand mine-manager works. He is responsible for a large unit of production; he works under trying conditions as to labor, in a region where the cost of supplies must always be high and the necessity for carrying large stocks imperative. He has to his advantage orebodies of which the regularity, even allowing for some over-emphasis in the past, is truly remarkable in gold mining, though not equal to that obtaining in other deposits. He has long had, also, such an abundance of capital as is unusual in gold mining. Provided that a profit could be shown as a result of increasing the scale of operations, building heavier machinery, or sinking deeper and more expensive shafts, the engineer on the Rand has needed unusually but to ask in order to receive. To managers struggling elsewhere with erratic orebodies owned by companies devoted to making the mine "pay its own way from the grass-roots down," the conditions on the Rand have appeared a little short of ideal. A visit, however, brings out the fact that the men who work there have their troubles as much as do their fellows on the Mother Lode or the Golden Mile.

Aside from the complications of labor regulations, taxes, and railway-rates growing out of the politics of a country in which there are divers races to consider, and few established industries, the greatest difficulties are connected with the very factor that might be assumed to be most favorable, namely, abundance of capital. I shall give later some statement as to what the amount of capital is, but, as regards the mine-manager, the essential factor is that the money comes from the public. He works not for owners but for trustees; the big Rand houses are only in small part actual owners of what they control and manage. While the consulting engineer of any of the big groups has, within his province, a remarkable freedom of action, and there are few engineers anywhere who occupy positions of greater responsibility and dignity than the leading men at Johannesburg, in other directions their freedom of action is definitely limited. The general policy of each house is determined by the financial managers and not by the engineers, and in formulating it the managers have always to regard the source of the capital, namely, the public market for shares. However excellent from an engineering point of view a project may be, it cannot be considered if it will unfavorably affect the market in anything more than a temporary manner. Such a situation has both advantages and disadvantages. Some, highly regardful of their position as trustees for others, will tend to over-conservatism in management. Others, relying on the market to make good any personal loss incurred, will take chances that they could not face without this recourse. On the whole, their responsibilities have been taken seriously by the Rand houses and the result has been a conservatism in management that is often considered excessive by outsiders. Coupled with this has been a cheerful optimism when it came to floating companies or effecting consolidations. To one on the side-lines it often seems that the

financiers concerned with the Rand are not averse to taking chances in the field that they consider their own, but are decidedly averse to their technical advisers adopting any such daring attitude.

It is right and proper that the technical methods adopted in mine-management should take cognizance of the source of the funds employed. If, however, in practice this means the toleration of expensive methods where from the point of view of technology alone cheaper ones are applicable, it is also proper that the extra cost should be duly set out so that there may be a clear understanding. The expenditure may be entirely proper judged as insurance, such as the interest charge on developed ore-reserves, or it may not. Whether it be a wise policy to incur the extra cost is a fit subject for consideration as a matter of policy, but it is not proper to lay down artificial conditions and then hold engineers responsible for costs; that this is done to some extent would be my criticism of present Rand mining practice.

The extent and scale of mining on the Rand is already familiar to my readers. It will suffice to recall here a few figures taken from the yearly report of the Transvaal Chamber of Mines. In 1915, 53 mines produced 31,331,316 tons, which after sorting out 9.62%, yielded 28,314,579 tons to be milled. The reduction works included 9396 stamps and 307 tube-mills, operated for an average of 316.69 days, with a duty per stamp equivalent to 9.53 tons. The total gold extracted was 8,722,919 fine ounces, valued at £37,264,992 equivalent to 26s.3d. per ton milled. The working cost averaged 17s.5d. per ton, the working profit 8s.5d., and dividends 4s.10d. per ton.* The contributions to the world's gold output now made annually by the Transvaal, including the outside districts, amount to about 40% and the total yield of the Rand to the end of 1915 is estimated at 106,941,089 fine ounces. The average number of white employees on the Rand in 1915 was 22,017, and of natives, 211,096. The number of rock-drills in use was 5675 and the amount paid for salaries and wages £13,501,291. The total value of stores purchased for consumption in that year was £10,889,115.

Originally small mines were opened along the outcrop. Later the deep-levels and still later the 'deep deeps' were opened and the period of consolidation began. Out of it has come the system of group-control with head-offices at Johannesburg, where each group maintains a general technical staff and responsible manager at each mine.

The consolidation and growth of the group system of control has proceeded to such an extent that virtually all the Rand mines are affiliated with some one of nine groups. There is much joint ownership and many of the properties have been financed by co-operation of several groups, as in the case of Daggafontein, which is now being re-opened by the Consolidated Mines Selection

Company, with the assistance of the Central Mining & Investment Corporation.

The Rand Mines consolidation, while independent, is closely affiliated with the Central Mining, both being 'Corner House'† companies and the outgrowth of the activities of Wernher, Beit & Co., which firm, as will be remembered, was represented on the Rand by the house of H. Eckstein. The Gold Fields organization grew out of the activities of Cecil Rhodes, and the Consolidated Investment Co. out of those of Barnato Bros. The General Mining & Finance Corporation is known as the Albu group. The Brakpan and Springs mines represent the growing Consolidated Mines Selection interest.

A general view of the business of mining on the Rand may be obtained from the following figures, taken from the report of the Transvaal Department of Mines and Industries for 1913, the last complete year before the War. Up to that time 103 mines had reached various stages of development or operation. Of these, 40 had become dividend-payers. The following figures show the main facts as to capital:

	Dividend-paying mines	Total of all companies
Net issued shares	£36,219,995	£59,797,942
Outstanding debentures	5,744,940	8,775,238
Unamortized premium on shares ..	4,960,142	8,176,744

The total dividends for the year amounted to £8,205,201, equivalent to 10% for the whole outstanding and unamortized capital, or 17% if only the dividend-paying mines be taken into account. This calculation neglects the value of plant, surplus, stores, and other items; it is concerned only with dividends and capital. It has, of course, nothing to do with what may have been paid for shares, only taking into account what the companies received, and assumes that property paid for in shares was of the real value represented by them. Taking all these facts into account the showing is undoubtedly a good one.

Another tabulation of some interest is that giving the gross yield of the Rand and the percentage paid out as dividends:

Year	Output £	Dividends, %
1902	7,179,074	29
1905	19,991,658	24
1908	28,810,393	30
1911	33,543,479	24
1914	34,124,434	24
1915	37,264,992	20

This again is a record much better than might have been anticipated by one familiar only with market-news, which deals rather with share-values than the actual results of mining.

Turning now to present-day problems in Rand mining, the most portentous is undoubtedly how to reduce the working expense per ton so as to save the decreasing margin between yield and profit. The necessity for some

*Owing to the fluctuation in exchange it is not possible to give the American equivalents accurately; as an approximation the pound may be taken at \$4.86 and the shilling at 24 cents, and the penny at 2 cents.—EDITOR.

†The name given to the headquarters of the original Wernher-Beit-Eckstein group.

change is indicated by the figures in the table below, taken from the reports of the Transvaal Chamber of Mines; to this I have added the dividend record as being through a long series of years the best measure of profits.

YIELD, PROFITS, AND DIVIDENDS ON THE RAND:

Year	Yield	Working		Dividends	
	per ton	cost	profit	per ton	
	£ s. d.	£ s. d.	s. d.	s. d.	
1902	2 2 0	1 5 9	16 6	10 3	
1903	1 19 8	1 4 9	14 11	9 4	
1904	1 18 6	1 4 4	14 2	8 1	
1905	1 15 10	1 3 6	12 6	7 2	
1906	1 14 6	1 2 2	12 6	7 0	
1907	1 13 11	1 0 10	13 3	7 8	
1908	1 11 5	18 0	13 5	8 1	
1909	1 8 11	17 1	11 6	9 9	
1910	1 8 6	17 7	10 6	7 1	
1911	1 7 11	18 0	9 7	5 8	
1912	1 9 0	18 8	10 0	5 5	
1913	1 7 9	17 11	9 6	5 8	
1914	1 6 6	17 1	9 0	5 8	
1915	1 6 3	17 5	8 5	4 10	

It will be noted that with only one exception the grade has fallen year by year and that only on three occasions has the working profit increased. These facts are brought out more clearly in the next table, in which the decrease or increase over the preceding year is shown. The figures are all the more significant since they relate only to the working-profit and take no account of increased capital changes, which have been heavy.

Year	Decrease in yield	Decrease in working-profit
	s. d.	s. d.
1903	0 4	1 7
1904	1 2	0 9
1905	2 8	1 6
1906	1 4	0 0
1907	0 7	0 9*
1908	1 6	0 2*
1909	2 6	1 11
1910	0 5	1 0
1911	0 7	0 11
1912	1 1*	0 5*
1913	1 3	0 6
1914	1 3	0 6
1915	0 3	0 7

*Increases.

Comparisons for any individual year are not exact, since a decrease in average yield shows at once in the working-profit, while the benefit of changes made in working-conditions lags behind. For the period as a whole the mining engineer has scored, since the total fall in average yield has been 14s.9d. and in working-profit only 7s.1d. Unless the increased capital charge be taken into account it is not feasible to present an absolutely exact comparison. To meet a situation such as portrayed above, three courses are open: (1) to increase the grade of the ore by selective mining or closer sorting; (2) to decrease the cost per ton by re-organizing the industry on a basis of larger units; (3) to improve the technical practice in both mine and mill so as to lower the cost and increase the saving. All three of these plans have been tried without complete success in any direction.

Selective mining, either by leaving low-grade blocks standing or leaving side 'reef' unmined, was urged as a panacea and with great vigor about 1909-1910, but, attractive as the plan sounds when urged by an enthusiastic advocate, it must be admitted that in practice it fails to meet the situation in anything more than a limited way. A recent instance, reported by the Crown Mines, for the quarter that ended March 31 last, may be cited as typical. It will be remembered that in 1915 and the early part of 1916 there was an abundance of native labor. Taking advantage of the opportunity, itself most unusual, the attempt was made to raise the grade of the ore by taking machines out of stopes, substituting hammer-boys, and narrowing the stoping-width. The average yield per ton was increased 0.5 dwt., but it was found impossible to maintain the tonnage under these conditions, despite the fact that 37 additional faces had been opened. The total yield was less and the cost per ton higher, so that profit decreased. It was therefore decided to revert to the old method of intensive production. As I shall indicate later, the cost of merely keeping open additional faces is much larger than is generally realized, and this, together with the doubtful net value of the ore left behind, shows that there is little hope from narrowing the stope-widths in depth along the Central Rand. The whole subject was discussed informally by W. W. Mein in a paper read before the South African Association of Engineers, and reproduced at length in the MINING AND SCIENTIFIC PRESS of September 24, 1910. Since Mr. Mein's paper appeared, results seem to have confirmed abundantly the ground he then took in favor of the wider stopes, though it is to be noted that none of the engineers who went in for selective mining have set out in detail their actual experiences.

The closeness with which it is desirable to sort is a matter upon which local opinion differs sharply despite the great tendency to standardization. So far no uniform practice has been evolved nor is there even unanimity as to whether or not sorting is desirable. It may be a coincidence merely, but on the Rand the coarse-crushing and sorting plants are seldom under the direction of the metallurgist, whose authority and responsibility begins only with the ore delivered to the stamp-mill bin. At some mines the sorting-plant is considered to be part of the mine equipment. At many the manager retains control himself and uses it as a sort of reducing and safety-valve to control the stream of ore flowing from mine to mill. Visiting a number of sorting-plants, I was impressed with the marked contrast between the irregularity of the work done by them and the general uniformity of the stamp-mill work. If one may judge from the recorded sampling of the rejected waste, there is great irregularity in the technical result. This, I believe, goes back to a fundamental condition laid down by the management, and to which both engineers and metallurgists must conform, namely, that however widely the ore may vary in gold content from day to day, the return from month to month must fall close together. The inevitable result is alternate crowding and starving of the

ore-house and consequent great irregularity in the closeness of the sorting. There are many other results of which I shall speak later, but it is sufficient here to point out that ore-sorting, despite the consideration that has been devoted to it, is still in an unsatisfactory state on the Rand. Whether it is cheaper to separate 'reef' from 'rock' that is, ore from waste, by hand in sorting-houses or to send the whole to the mill will depend in large part upon how the ground is broken and how the partings occur in the ore, and it is not to be forgotten that conditions vary greatly from point to point. It is not feasible to attempt to discriminate in the ore-house between profitable and unprofitable banket, and it is rarely practicable to pick out interbedded quartzite. At best, only barren quartzite broken in mining can be picked out. It is impossible for an outsider to say what plan is more economical on the whole and it is entirely possible in theory, as seems to be true in practice, that sorting should be profitable at one mine and not at another. If so, it is probable that this is due to methods of mining in part conditioned by differences in the lode and to costs of milling. Speaking generally, I venture the opinion that the work of sorting as now conducted is one of the weakest points in local practice. That the tendency on the Rand as elsewhere is to eliminate it, substituting larger mill-capacity with lower operating-cost, is shown by the fact that the percentage of waste sorted out has fallen with fair regularity from 17.25 in 1904 to 9.62 in 1915. Improvement in sorting-practice, if sorting is to be continued, is possible in the direction of better sizing of material, more by-passing, and to some extent in better arrangement of the plant. No great improvement is possible, however, so long as the end sought varies from day to day and the most inefficient 'boys' gravitate to the ore-house. What is needed is first a definite policy. In too many instances the matter has been controlled by the necessity of feeding a mill too large for the mine.

Whether we look to selective mining or to sorting, there seems little good in increasing the grade of the ore handled, and while we may theorize at length as to causes, the fact remains that year by year the ore treated is poorer. This decline seems likely to continue till it reaches a point equal to the lowest operating cost that can be held. Capital losses may be disguised, but in mines such as the Rand, where bonanza orebodies are not to be anticipated, it is hardly probable that any mine will long run at an operating loss.

The second method of meeting the problem of decreasing returns is by re-organization of the industry upon the basis of larger units. This takes the forms of (1) increase in the size of the actual plant-units; and (2) increase in the size of management and financial units. Both have been tried on the Rand and each plan has something to its credit, but against each there has been a reaction. The first and most natural step was to open larger mines and build larger mills so as to spread the general expense over a greater tonnage. In some cases the actual unit cost per ton was lowered by increasing the plant, in others it was only the stand-by or some other

part of the 'overhead' that was brought down. Occasionally both factors were favorably influenced. The net effect was a considerable reduction in working-costs per ton, particularly in the years 1906 to 1908 when the average working-cost was decreased by 4s.2d. per ton. Since 1908, costs have remained nearly stationary; however, it increased in the years 1911 and 1912, when the most selective mining was being done. The culmination of the move toward 'wholesale' mining was in 1908. That much abused term came in for a great deal of discussion in the years 1908 to 1910, when, as I have already indicated, there rose up certain sturdy prophets who preached that the system was a delusion and a snare and the temptation to its abuse so strong that no mining man was safe if left alone within the sound of its advocate's siren voice.

In a paper before the Institution of Mining and Metallurgy in 1909, W. R. Feldtmann discussed the whole subject with notable clarity and sanity. He pointed out that wholesale mining is possible under these conditions:

1. Where it is possible to reduce the cost per ton without reducing to a corresponding extent the product per ton. The effect is then to shorten the life of the mine, but, as there is a larger profit per ton, so there is a larger working-profit during the life, as well as a higher rate of profit per annum. To which may be added that the final profit is increased by the interest earned due to the gold being won earlier.

2. Where the cost per ton is reduced and the grade is also reduced. This results in less profit per ton and shortens the life, but the total profit is increased because there is more profit per ton on the original ore, plus whatever profit may be won from the added ore.

3. Where the cost per ton is reduced but the ore added is below the ordinary cost per ton. This does not shorten the life of the mine, but it increases both the total and the annual profits so long as the ore added gives a yield above the unit-cost.

The general idea embodied in wholesale mining has been widely applied in other industries, particularly in shipping. Low back-freights are a constant feature of the transportation business. The matter has been before the courts of many lands and it has been repeatedly held that it is no injustice to other shippers for a carrier to transport at a reduced rate such goods as would otherwise not be moved, so long as the rate does not fall below the actual cost of the transportation. Any contribution toward general expense from such a source is held to be so much clear gain, so far as the transportation company and other shippers are concerned. It is better for steamers to carry china-clay from Cornwall to America, for example, than to travel with water-ballast, so long as the rate on the clay covers the cost of loading and unloading and is more than the cost of pumping water-ballast in and out, delays being of course taken into account. The same principle applies in mining and particularly to Mr. Feldtmann's third case, which is the only one concerning which there is any material difference of opinion. When a lode has been opened and it is a question of wide or

MODDERFONTEIN DEEP, SHOWING METHOD OF WORKING THROUGH TWIN SHAFTS, WITH INDEPENDENT STEAM-PLANT

narrow stoping, there can be little doubt that, so long as the additional rock contains more recoverable gold than the actual cost of saving it, there will be profit in the wider stopes. It is perhaps not so easy to determine whether or not a low-grade block shall be worked or left standing. Decision of such matters requires intelligent care and conscientious judgment, but that does not alter the principle obtaining, and in general along the Rand large-scale mining is recognized to be correct practice. A reduction plant, of course, should be run upon the highest-grade ore with which it can be steadily fed, but in actual practice narrowing the stopes has usually resulted in idle stamps or crushing waste. A large mill is a constant temptation to poor mining.

The scale of production upon the Rand is indicated by the table below, for December 1915.

Tons produced	Number of mines
Under 25,000	14
25,000 to 50,000	16
50,000 to 75,000	17
75,000 to 100,000	1
Over 100,000	1

In each case the production is by companies and not by individual shafts or mills; in fact, each is really a group of mines. Of the four large concerns, Crown Mines leads with 240,000 tons from several shafts, Randfontein Central comes second with 217,800 tons, East Rand Proprietary is third with 196,418, and Knights Deep is

GEDULD SLIME-PLANT. PACHUCAS IN BACKGROUND

fourth with 105,500. In point of fact the Rand companies operate on a basis of 1000 to 2000 tons per day—large figures, but not uncommon in mining and by no means over-shadowing.

The relationship of working-cost to tonnage is not close. The following table gives the figures of tons milled and total working-costs for a few representative properties in 1915.

RELATION OF TONNAGE TO COST, 1915

Mine	Tons milled	Working-cost	
		s.	d.
Total and average.....	28,314,519	17	5.0
Crown Mines	2,501,450	16	2.0
East Rand Proprietary.....	1,983,600	19	1.1
Randfontein Central	2,466,520	17	11.0
Knights Deep	1,172,920	12	2.0
Rose Deep	789,700	16	11.0
Brakpan	725,168	18	0.2
Simmer Deep	769,100	15	1.0
Robinson	688,800	13	7.0
Geldenhuis Deep	638,800	21	6.0
City Deep	677,200	20	5.0
Modderfontein B	509,700	15	10.0

Even more striking is the following table quoted from the annual report of Crown Mines and covering the period of expansion of output.

Year	Tons milled	Working-cost	
		s.	d.
1908	466,320	15	6
*1909	244,065	14	8
†1909	740,924	‡17	0
1910	1,514,000	‡18	4
1911	1,618,500	‡19	4
1912	1,920,700	‡18	4
1913	2,195,600	16	5
1914	2,287,000	15	7
1915	2,497,000	16	2

*First half-year. †Second half-year. ‡Including accumulated slime and dump treatment.

The total tonnage for the whole 17 years since the opening of the mines now belonging to Crown Mines has amounted to 15,722,215, and the average working-cost has been 17s.7d. These figures would seem to indicate that increasing the tonnage has not as yet been reflected in a lower operating-cost. This is a rather surprising circumstance, though it is to be remembered that working-costs do not tell the whole story. Referring back to the first table given in this article it will be noted that there is a considerable margin between working-profit and dividends per ton. This is represented by capital expenditure, debenture-interest, and various other expenses not included in Rand practice under working-costs. One of the confusing conditions that must be kept in mind in a study of Rand accounts is the large current expenditure regularly charged to capital account.

It remains to inquire why the expansion of output has not influenced the working cost to a greater extent. The working-cost includes two elements: unit costs and overhead. The former covers such items as breaking, shoveling, tramping, hoisting, milling, and gold realization. It is clear that such items of cost are to a large extent independent of mere quantity. In order to affect them it is necessary to make changes. To haul more

tons does not mean that the cost will be lowered unless the track be improved, the trucks made larger, the motive force more powerful, and the power-cost reduced. In order to lower unit-costs by expansion, it is necessary to change methods of work and, speaking of the Rand as a whole, there has been much less of this than of mere company consolidation. In most instances Rand consolidations have only resulted in more units of production being controlled from one centre. The same methods continued to be used and often the same number of small mines continued to be worked. The only economy that could result from such consolidations would be in overhead expenses, and in considerable part these are not really reflected in working costs. Without going exhaustively into the matter, it appears that that part of the general expense assessed to working-cost in mines of 200,000 to 300,000 annual tonnage amounts to about a seventh of the total. The actual fixed expense not subject to control of the manager is larger, amounting to about two-fifths of the total. Even if, through consolidation, the admitted overhead had been materially reduced by distribution over a larger tonnage, it could not have greatly affected results. In order to show any considerable profit other than that arising from quick mining of the gold and lower capital charge per ton, it would be necessary to change methods; to make one mine out of a number of them. That has not been done on the Rand, although Crown Mines has attempted it and has spent a large sum on main-haulage roads, central deep shafts, and similar work. Randfontein Central, after building the largest single stamp-mill in the world, and an excellent mill it is, never centralized its milling until 1916, but continued to operate both old and new plants at part capacity only. It is because of such things that the big consolidations of the Rand have not made good on their anticipations; in fact, the consolidations have taken the form of joining two or more existing mines as going concerns or of adding non-producing claims to the assets of a producing mine. In the first case it has too often happened that the old plants have been continued in operation with little change. As already indicated, there could be little increase in earning power through such a consolidation. When non-producing claims are joined to a producing property it is not always realized that the present value of the claims is largely a function of time, when they begin to produce. To lengthen the life of a mine 10 years when it already has a life of 10, may be represented by the factor 2.03, but to add 10 years to the life of a mine that already has 20 years assured is represented by the factor 1.0. This matter of present value is not sufficiently understood by mine-investors and they have too often been allowed to overlook it. A consolidation that does not increase output involves temporarily a loss and if production be long deferred even the final profit may be small. In several cases consolidation was deferred until the mines in depth reached a physical change in the lode, so that figures based upon past performance proved misleading.

(To be continued)

Magmatic Segregation and Ore Genesis

By JOSEPH T. SINGEWALD, JR., Ph.D.

The preparation of the following article has been stimulated by the recent monograph on the magmatic sulphides by Tolman and Rogers.* The relations there described for the sulphides recalled so many similar relations observed in my studies of titaniferous magnetites, that the genetic conclusions based on them aroused more than usual interest. Though one of the latest groups of ore deposits to be definitely recognized, through the notable work of J. H. L. Vogt 25 years ago the magmatic segregations were firmly established as one of the major types; and it has been felt by many that the mode of formation of these deposits was so clearly understood that they constituted a group concerning the genesis of which no further question existed. More thorough petrographic studies of many examples of deposits classed with the magmatic segregations and especially the metallographic investigations of ores during the last decade, have accumulated more evidence to show that the mineralization was not so simple and did not conform strictly to the conception of a magmatic segregation in the sense in which that term had generally been employed. The time has arrived for a recapitulation of these discordant data and a remolding of our conceptions in harmony with them.

The term magmatic segregation was borrowed by the economic geologist from the petrographer, and used in the petrographic sense. Its application for the explanation of the genesis of certain ore deposits seemed plausible. It is a matter of common petrographic knowledge that no large body of igneous rock is of uniform composition, but that frequently the composition of a portion of the mass departs widely from the average. Consequently there were forces at work prior to or during the consolidation of the molten magma which caused local segregations of certain of its constituents. The nature of these forces has long been a matter of discussion and speculation, but unanimity of opinion has not been attained, and there is no thoroughly satisfactory explanation of the process known as magmatic segregation or differentiation. The usual manifestation of the phenomenon is in local accumulations of the more basic constituents of the magma. The basis for the application of this process as an explanation of ore genesis rests on other observations in the field of petrography. There is present in almost all igneous rocks a group of opaque minerals, occurring as accessory constituents and with euhedral forms, the most common representatives of which are the sulphides of iron, frequently cupriferous, and the oxides of iron, frequently chromiferous or titaniferous. On account of their commonly euhedral forms,

these minerals are regarded by petrographers as the earliest constituents of the magma to crystallize. Furthermore, these minerals are concentrated together with the basic silicates in the process of rock differentiation.

There are many ore deposits, world-wide in their distribution, possessing certain common characteristics, among which may be mentioned: (1) the ore minerals consist of one or more of the accessory opaque minerals common to igneous rocks; (2) the enclosing rock is always an igneous rock, and usually basic in composition; (3) the gangue minerals of these deposits are the same as the constituent minerals of the enclosing rock; (4) the orebody frequently passes by a gradual transition into the igneous rock by a decrease in the amount of the ore minerals and an increase in the amount of the silicates. These deposits appeared to be an integral part of the igneous rock in which they are found and to represent an extreme facies of the product of rock-differentiation. Consequently they were established as an independent group of ore deposits to which the name magmatic segregation was applied. The group was subdivided by Vogt into three divisions according as the metal occurs in the native, oxidic, or sulphidic form. Segregations of native metals as primary ore deposits are of little economic importance, but the placers derived from such segregations of native platinum in the Urals constitute our principal source of that metal. Segregations of oxidic ores are the only source of chrome ores, and such segregations include countless deposits of titaniferous iron ores, as well as important deposits of non-titaniferous iron ores. Segregations of sulphidic ores include the nickeliferous and cupriferous pyrrhotites and probably a few copper-sulphide deposits. The metallic content of the segregations of the native metals usually is sparsely disseminated through the rock, and on account of the few examples of these and their minor importance, the propriety of regarding the metal as a segregation and product of crystallization from a molten magma has been little questioned. The segregations of oxidic ores usually occur well within the igneous mass, and there are so many admirable illustrations of gradation from rock with feeble concentrations of metalliferous minerals to important orebodies that no particular significance has been attached to the observation that the ore-minerals are often later than the silicates, and the conception of a segregation and solidification from a molten magma rarely has been challenged. The position of the sulphidic deposits, however, has been somewhat dubious from the start. They tend to occur on the periphery of the igneous mass; the sulphides often penetrate into the wallrock; it was early recognized that in part

*M. & S. P., April 21, 1917.

at least the sulphides are distinctly later than the rock-forming silicates, and the rock itself has frequently undergone considerable alteration. Consequently many geologists have regarded them as hydrothermal deposits. A most interesting feature of the controversy over the genetic position of these sulphidic ores has been that the nickel deposits of Sudbury, Ontario, cited by the advocates of the magmatic origin as a typical illustration of that type, is one example to which most serious objection has been raised by those contending for a hydrothermal origin. In view of the departures from the conceptions based on purely petrographic phenomena and concepts seen in these deposits, it is interesting to compare the treatment of the problem in four recent textbooks on ore deposits. These four are: R. Beck, *Die Erzlagerstätten*, 1909 (3rd edition); Beyschlag-Krusch-Vogt, *Die Lagerstätten der nutzbaren Mineralien und Gesteine*, 1910; W. Lindgren, *Mineral Deposits*, 1913; L. DeLaunay, *Gîtes Minéraux et Métallifères*, 1913. Beck, in defining magmatic segregations, says: "In many instances there took place in the rock either before or during solidification from the molten state a concentration of the ores into irregular masses.* * * In spite of the concentration into a limited space, the ores of such deposits remain, what they as scattered particles in the rocks in question are, namely, accessory constituents." Commenting on Vogt's observation that in certain of the Swedish and Norwegian titaniferous iron ore deposits the silicates formed first and then the titaniferous magnetite, he says, "those are departures from the rule otherwise prevailing for eruptive rocks that the iron ores belong to the earliest minerals to separate." In all chrome deposits which he cites for the sequence of crystallization, the chromite is the earliest constituent. Of the sulphidic deposits, on the other hand, he says, "The strict proof of segregation from a molten magma cannot always be established with the same degree of sharpness * * *. For a great many occurrences, which numerous authors consider a direct segregation from eruptive rocks, one must at least consider probable a later secondary re-crystallization of the ores by aqueous processes which brought about a partial migration and an impregnation of the wallrock." These conclusions are based largely on his own work in 1902-3 on the deposits of nickeliferous pyrrhotite and chalcopyrite at Sohland in Saxony, where he found that ore deposition took place by replacement subsequent to the hydrothermal alteration of the rock, though he believes both followed immediately after its solidification. With the exception of the treatment of the sulphidic ores, the position of Beyschlag, Krusch, and Vogt is similar to that taken by Beck, their ideas being largely those developed by Vogt. Their conception of the genesis of these ore deposits is that, "In the same manner in which larger masses of mica and feldspar can collect out of a granite magma, segregation of ores can take place, as for example magnetite, titaniferous magnetite, chromite and pyrrhotite, in such igneous rocks which normally carry these ores as accessory constituents." They call attention to the fact that the

ore-minerals followed by the iron-magnesium silicates are the earliest constituents to crystallize in most eruptive rocks and they are also the constituents that migrate in magmatic differentiation. Magmatic segregation is distinguished from ore deposition, in which mineralizers participate, as follows: "The genetic difference consists essentially in that the magmatic segregations result from a single differentiation-process of the magma, whereas in the case of the pneumatolytic and contact metamorphic deposits the metallic content originally belonging to the magma is transferred to an aqueous or gaseous solution and later deposited from this through new processes." Though in most cases the two groups are considered as sharply differentiated, they admit occasional intermediate stages in which magmatic differentiation is accompanied by pneumatolytic or pneumato-hydro-genetic processes. They definitely state that the chrome ores crystallized out of a magma, and that the formation of the titaniferous magnetites "depends on a pure magmatic separation, not accompanied by special pneumatolytic processes," and that the process differs from ordinary rock-differentiation only in that it has proceeded much further. The characteristic association of some titano-magnetite with the sulphides is taken to indicate a genesis for the latter ores analogous to that of the titaniferous magnetites. In further substantiation of the magmatic origin of the sulphides is the statement that secondary alterations, such as uralitization before ore deposition or contemporaneous with it, has not in general occurred. They emphasize the fluidity of the molten sulphides and their consequent ability to penetrate into minute crevices and cracks, and accordingly they have proposed to classify intrusions of molten sulphides into the country rock under the name of injected sulphide-deposits. In such an interpretation of a number of the most important examples included under this subdivision, however, they stand almost alone.

Deposits of this character are classed by Lindgren as 'mineral deposits formed by concentration in molten magmas,' concerning which he says: "Certain kinds of mineral deposits form integral parts of igneous rock-masses and permit the inference that they have originated, in their present form, by processes of differentiation and cooling in molten magmas." Of the oxidic ores he says chromite appears in all cases to be the earliest consolidated constituent, but that the titaniferous iron ores have as a rule crystallized after the silicates; but concerning the latter he says further: "Petrographic research has long ago shown that ilmenite with magnetite is one of the earlier products of consolidation in magmas and is contained in almost all diabases, basalts, and gabbros* * *. The larger masses of ilmenite are simply facies of the rock itself produced by concentration from the same magma." Lindgren's position concerning the sulphides is almost identical with that of Beyschlag, Krusch, and Vogt, as evidenced by such statements as, "Some of the magmatic sulphide-deposits are simple basic rocks abnormal in containing much pyrrhotite, chalcopyrite and pentlandite," and, "Some deposits in which

the ore consists mainly of solid pyritic minerals present features which can hardly be explained otherwise than by actual injection of molten sulphides," in spite of his admission that "on the whole the sulphides are the latest products crystallized." In reply to the advocates of a hydrothermal origin for some of these deposits, he charges them with having confused secondary changes with primary deposition. DeLaunay's treatment of these deposits differs considerably from any of the preceding. The first five divisions of his genetic classification of ore deposits are the following:

1. Deposits of included mineral.
2. Deposits by segregation.
3. Peripheral sulphide segregations.
4. Igneous metamorphic contact-deposits of the Banat type.
5. Impregnations by diffusion from deep-seated sources, (inclusive of pyritic masses).

"Deposits of inclusions are those where a useful mineral occurs in an igneous rock in the same relation as the other constituent elements." This division is of theoretic rather than practical importance, and includes only native metals and oxides present as normal accessory constituents of an igneous rock without the intervention of mineralizers. The segregation deposits, he says, might be regarded as having been effected without the intervention of volatile constituents; nevertheless, the general opinion today is that water and probably other mineralizers have played a rôle, though he considers them formed in a medium poor in mineralizers. The ores are native metals and oxides. The peripheral sulphide segregations, he says, have usually been considered examples of true segregations which differ from the internal oxidic segregations by their position and nature. DeLaunay believes it necessary to separate them entirely from the true segregations, for there has been a concentration of sulphides not only in the rock but at its contact, and they appear to him to be a parent to contact metamorphic deposits which are formed when the wall-rock is limestone. They represent a type of ore deposition in which mineralizers are more abundant and active than in the preceding. The close relation postulated between these deposits and typical contact metamorphic deposits indicates clearly that he does not look upon them as representing a crystallization from a molten state. The mineralization of the last group is analogous to that of the fourth, the types of deposits included under it being formed where the country rock is other than a carbonate rock. It includes most of the deposits classified by Beyschlag, Krusch, and Vogt, as injected sulphide deposits. There are no sharp lines of demarcation between these groups, as DeLaunay recognizes a complete transition from purely igneous deposits to hydrothermal veins, and indicates that in some instances it is difficult to decide between fusion and solution.

In an attempt to settle some of the doubtful points concerning the mode of formation of the sulphidic ores usually classed as magmatic segregations, C. F. Tolman, Jr., and A. F. Rogers of Stanford University, as a result

of a comprehensive petrographic and metallographic investigation, formulate statements which they find applicable to all the deposits studied. The most significant of these are: (1) the first minerals to form are olivine, the pyroxenes, and the feldspars; (2) magmatic alteration of the silicates often takes place prior to the formation of the ore minerals. The most common change is that of pyroxene to hornblende, but easily distinguishable from the hydrothermal process of uralitization; (3) the ores replace the silicate minerals but without reaction rims; (4) the ores are introduced one after another in the following invariable sequence: magnetite and ilmenite, pyrrhotite, pentlandite, and chalcopyrite. There is a certain amount of replacement of the earlier ore minerals by the later ones; (5) hydrothermal alteration is distinctly later than the period of ore deposition.

These observations led them to a theory of genesis more nearly analogous to that of DeLaunay than any of the others mentioned above. The fact that the ore minerals replace the silicates without the formation of metallic silicates by reaction is interpreted to mean that the ores were not introduced in a molten state, but that the same agency that brought in the sulphides removed the dissolved silicates, indicating the presence of active mineralizers. The alteration of pyroxene to hornblende is further evidence of the presence of mineralizers. Consequently they conclude that mineralization took place at a temperature below the melting point of the ores, and that they were held in solution through the agency of mineralizers. On the other hand, that ore deposition took place under conditions different from those of non-magmatic high-temperature deposits is shown by the absence of the secondary silicates characteristic of ordinary pneumatolytic and hydrothermal processes, or that, where present, they belong to a distinctly later period. They conclude, therefore, that the magmatic ores "have been introduced at a late magmatic stage as a result of mineralizers." The direct evidence presented by Tolman and Rogers is derived from the sulphide deposits, but the presence of a titaniferous magnetite in these, together with numerous references in the literature to the silicates preceding the ores in order of crystallization in deposits of titaniferous magnetite, led them to infer that the same observations and conclusions apply equally well to the oxidic ores. My own experience with titaniferous magnetites corroborates the correctness of this inference. The relations between the ore-minerals and silicates in the sulphide ores figured and described are repeatedly duplicated in thin sections and in polished sections from all occurrences of titaniferous iron ores in the United States. Titaniferous magnetite later than the silicates and replacing them is seen in nearly every section made, though many of the contacts of the two sets of minerals show what L. C. Graton and D. H. McLaughlin have recently termed mutual boundaries, that is, boundaries that give little evidence of the sequence of the minerals. Only rarely is there unmistakable evidence of primary silicates distinctly later than the ore. The replacement of the silicates by the ore has not been accompanied by

the formation of reaction-silicates and in several instances hornblendization has preceded the deposition of the ore, these phenomena being in harmony with the nature of the mineralization in the case of the sulphide ores. If segregation takes place without the intervention of mineralizers one might expect the deposit at Iron Mountain, Wyoming, to afford such an example. The orebody there occurs as an almost pure mass of titaniferous magnetite cutting the anorthositic country-rock as sharply as any igneous dike ever pictured. Yet the numerous olivine crystals which occur locally in the ore are rounded and embayed without the formation of reaction-silicates in exactly the same manner as in other occurrences. The deposit suggests an injection from a basic magma analogous to a pegmatite from one more acidic. In other cases, particularly at Grape Creek, Colorado, the introduction of ore has been accompanied by alteration of the feldspar, so that the magnetite is separated from it by a band of hornblende, indicating an activity of mineralizers greater than usual. The Minnesota deposits conform for the most part to the general rule that the ore is later than the silicates, and afford some examples of hornblendization preceding or contemporaneous with ore deposition, but also furnish instances of feldspar and pyroxene later than the ore. An excellent example of an iron ore deposit in a basic igneous rock, giving unmistakable evidence of active participation by mineralizers in the formation of the ore, is afforded by the Tofo deposit north of Coquimbo, Chile, now being worked by the Bethlehem Steel Co. This consists of a large mass of comparatively pure magnetite forming the top of a hill on the east side of the coast-range and occurring within a large area of gabbro rock. The igneous mass has undergone considerable differentiation, and various rock-types are represented in the vicinity of the orebody from highly feldspathic to almost pure ferromagnesian silicate rocks, some of which occur as dikes. The broader relations of the orebody are such as to suggest at once a magmatic segregation; but, at the same time, there are features suggestive of pneumatolysis. Adjacent to the ore are numerous stringers of magnetite in the country-rock, many having a thickness no greater than a knife-blade, which traverse it in such a way as to preclude the entrance of molten oxides. It can be explained only on the basis of the high liquidity at a lower temperature which would be imparted by the presence of abundant mineralizers.

The argument for the participation of mineralizers in the formation of magmatic deposits is plausible also from the general standpoint of ore genesis. Processes in nature representing different stages of a sequence from a given starting point are not usually separated by a hiatus. It is generally accepted today that igneous magmas are the primary sources of the metals, and modern genetic classifications group ore deposits according to their position or relation to the original source. It has been customary, however, to draw a sharp line between one group of deposits assumed to be segregated from the molten magma and solidified with it, and such

groups as represented deposition of material extracted from the magma by mineralizers and constituting the pneumatolytic and hydrothermal deposits. DeLaunay's classification recognizes no such gap in the sequence of mineralization, but postulates a gradually increasing participation of mineralizers and hence a gradation from one stage to the next. It goes even a step farther and indicates that concentration of the metallic content of a magma to the extent necessary to form important orebodies takes place only when the necessary migration of the metals is aided by the presence of mineralizers, for the only group recognized by him in which mineralizers did not participate contains no deposits of economic importance, and it is only in the group in which mineralizers begin to play a part that ore deposits are represented. There have been two lines of thought in an effort to explain ore genesis, namely, that represented by the French school which has always emphasized the rôle of mineralizers, and that of the American and German economic geologists whose tendency has been to draw a sharp line of demarcation between the magmatic and the non-magmatic deposits. The work of the American and German investigators has so greatly preponderated during the last quarter of a century in the development of the science of economic geology that the views of the French school have been largely overshadowed and have not received the attention that they merit. The monograph by Tolman and Rogers will serve to establish among American economic geologists the ideas advanced by the French school. The corroborative evidence offered by the iron ores, as set forth in this paper, will serve the same purpose. A new study of the chrome-ores, with this interpretation in mind, apparently would place them in harmony with it. They now seem to be an exception, and to represent a direct segregation as the first product of crystallization from a molten magma.

BEFORE the War Germany held 28.8% of the proved deposits of iron ore in Europe, or 13% of those of the world, and France 24 and 11% respectively. In 1913 Germany worked up 47,000,000 tons of iron ore, extracting therefrom 17,500,000 tons of iron, of which 14,000,000 tons of ore, representing 7,750,000 tons of iron, was imported. In the same year France produced 21,500,000 tons of ore, of which 20,000,000 came from the Department of Meurthe-et-Moselle, three-quarters of which came from the Briey basin. Germany, before the War took 4,000,000 tons of iron ore from Briey, 3,500,000 from Spain, and 4,500,000 from Sweden. "As the War put an end to her imports from Spain," says Dr. M. Schlenker, "without the French iron ores it would have been impossible for the German iron industry to have met the enormous requirements for munitions."

IRON ORE from the Tofo mines in Chile will soon be brought in large quantities to Baltimore for the use of the Bethlehem Steel Co., in a fleet of six ships belonging to that concern. It is estimated that iron can be produced from these ores at Baltimore at a unit cost of 7 to 8 cents.

Drill-Sharpening

The United Verde mine, at Jerome, Arizona, daily requires an unusual number of drills, because the ground is excessively hard. Special arrangements have been made for drill-sharpening. These have been described by Frank Richards in the *Engineering News*. Mechanical drill-sharpeners are in use. The average number of drill-bits sharpened daily is 1800, and this requires the united effort of three men in sharpening, three helpers heating and punching steel, one man tempering, and one utility man. The work is all done in one 8-hour shift.

The dull steel is collected on the various levels of the mine, brought to the surface, sorted, and delivered to the blacksmith-shop by cars of special design. The equipment of the sharpening-plant comprises an oil-

punching-machine, Fig. 3, has an air-plunger that is controlled by an oil-cylinder. The punch is held by a chuck that forms part of the piston. Alignment of the steel and punch is ensured by an automatic centering-clamp. The punch has increased the capacity of the sharpening-plant 50%. The steel is punched, sharpened, and blown out in one heat. Careful supervision of the shanks has greatly reduced the breakage of pistons and drills.

The Champion mine, at Platteville, Wisconsin, has

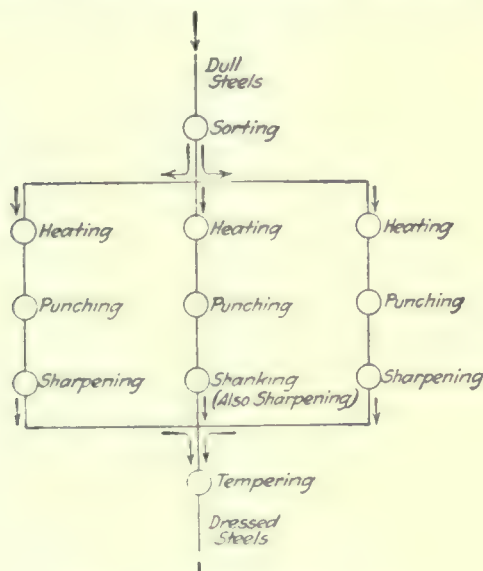

FIG. 1. SEQUENCE OF OPERATIONS.

furnace, a Davies air-operated punching-machine, a Leyner drill-sharpener, and a Davies 'blow-gun.' The work of handling and sharpening the steel has been systematized so that a dull drill entering at one end of the shop leaves ready for duty at the other end, as shown in Fig. 1. The drill-steel is hollow. The helper unloads the dull drills upon arrival, places the drill in the furnace, and when it has reached the proper heat, he removes it and places it in the punching-machine. He then passes the drill to the blacksmith, who sharpens it in the Leyner machine. When a large number of drills have been sharpened they are taken to the tempering-furnace, where they are heated to the proper temperature and delivered to the slack-tub. Tempering is done by plunging the bits into water and the shanks in oil. The utility man does the grinding and dressing of the shanks. Fig. 2 shows the arrangement of the sharpening unit. The forge has a capacity for 25 drills at a time. The

FIG. 2. THE EQUIPMENT.

a special arrangement for sharpening drill-steel, as described by J. E. O'Rourke, also in the *Engineering News*. The shop is centrally situated, as the steel for four mines is all handled in this establishment. A Sullivan sharpener and a Denver Fire Clay Co. oil-furnace are in use. The dull steel, on arrival from the mines, is sorted and placed in racks arranged for the purpose.

FIG. 3. PUNCH FOR HOLLOW STEEL.

From the rack it goes to the upper deck of a double-deck stand in front of the forge, as shown in Fig. 4. Nine drills can be accommodated in the furnace at one heating. The most satisfactory heat was found to be about 1650° F. To determine the proper temperature a pyrometer was used. It was held in position in the fire by means of an attachment bolted to the forge, as shown in Fig. 5. The blacksmith stands on one side of the double-deck stand and his helper on the other, as illustrated in Fig. 4. The dressing of a drill-bit requires 30 seconds. Two methods of tempering are practised. In one the temperature of the steel is lowered by partly quenching and drawing the temper to the desired color; in the

other by plunging the bits into a brine of sal-ammoniac, saltpetre, and sodium bromide, covered with six inches of No. 2 quenching-oil, the bit remaining in the liquid until thoroughly cooled. Brine causes a more rapid contraction of the granules of the steel than water, though

gal. of warm oil is always available. Fig. 4 shows the plan and two sections of this shop, and Fig. 5 illustrates the attachment of the pyrometer. The type of bit shown in Fig. 6 has been found to be best adapted for the limestone of this district. The total cost of this shop complete was \$2300.

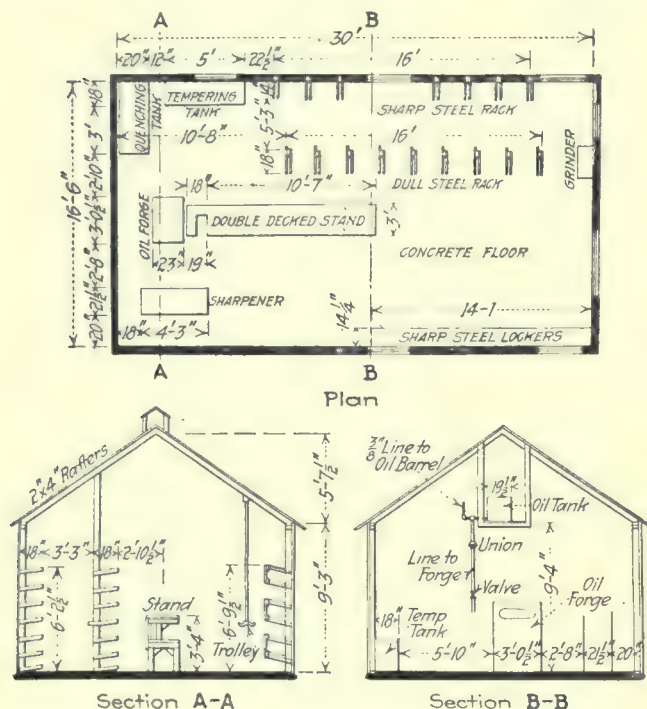

FIG. 4. PLAN AND SECTIONS OF SHOP.

this rapid action is retarded by the protecting film of oil. The bromide reduces the effect of over-heating. The other ingredients of the solution are added to soften the water. When the drill-bits have been sharpened and

Electro-Deposition of Antimony

*Antimony fluoride and free hydrofluoric acid give the best bath for the electro-deposition of antimony. The bath used contains 5% of antimony as fluoride and 3% of free hydrofluoric acid. A suitable organic addition-agent must be used to prevent a crystalline structure. These baths work easily and without deterioration or undesirable change, if the proper quantity of addition-agent is maintained and if the ordinary precautions in plating are observed. Without the organic addition-agents the deposits are rough and crystalline. The smoothest, thickest, least crystalline deposits are obtained by adding aloin, beta-naphthol, alpha-naphthol, or resorcinol. The addition-agent, 0.025%, must be added every 12 hours during the electrolysis. The deposits are gray and finely crystalline, except that too large a quantity of some addition-agents makes the deposits darker and more glossy. This result can also be produced by adding small amounts of clove oil (0.0012 cc.) along with any of the other addition-agents. The deposits are brittle, like ordinary cast antimony, hence if a plated article is bent the deposit will crack. Aloin is the cheapest of the satisfactory addition-agents. If the deposit becomes dark or shiny in color or tends to crack, less addition-agent must be used; a crystalline rough structure indicates the need. Excess causes the deposits to crack. A current of 7.4 amp. per sq. ft. is used. The deposits are less smooth with 10 amp. and, with still higher currents, they became rougher, especially when thick cathodes are being made. The voltage is 0.65 with the cathode midway between the two anodes, which were 4 to 5 cm. apart. The current efficiency is nearly 100.

THE CHINESE government plans to do her own cash-smelting. Enormous profits have been made by various companies, especially Japanese, buying up copper coins in China and melting them down, the amount of copper exceeding the money value of the 'cash.' An organization with a working capital of \$10,000,000, of which the ministry of finance will advance \$1,000,000, has been effected. It is planned to establish a smelting works at Tientsin, with branches in several provinces. Chinese copper cash contain from 50 to 90% of copper, and yield also tin and zinc. These coins have been hoarded for centuries and the quantities available are almost inexhaustible. Copper cash recently exported to Japan at the rate of 6000 tons per month realized a profit of \$60,000,000 silver on importations from northern China alone.

FIG. 5.

FIG. 6.

tempered they are placed on another rack. The final operation is the grinding of the end of the shank, which must be true. The grinding and truing of the shanks is done in a bench-grinder. After grinding, the drills are replaced in the rack ready for use. The oil is stored in a tank outside the building and heated by means of hot water circulating through a coil of pipe. About 50

Pyrite, Sulphur, and the Manufacture of Sulphuric Acid

*Up to the middle of 1915 American manufacturers were able to supply domestic needs for sulphuric acid, but as the War-demands of Europe became more acute, and more and more was demanded in the production of munitions, the call upon the makers of sulphuric acid became so great that the manufacturers had great difficulty in meeting their contract requirements while at the same time providing for the domestic trade. The effect was, war contracts being given preference, that the makers of soluble or acid phosphates were hard put to obtain sufficient sulphuric acid. This demand could be met in but one way, namely, by increasing the output of the existing plants and by erecting new ones. This was done on a large scale, with the inevitable result that the available supply of the basic material—in this case pyrite—had a direct effect upon acid-production, so that when, owing to ocean-shipment conditions, particularly during the past three months, the supply of foreign pyrite reaching this country was greatly cut down, the manufacturers of acid turned to sulphur as a base. Some of the largest makers at present are using sulphur, while others are seriously considering a change to it. This is borne out by every report from sulphuric acid manufacturing centres. To make up for the stringency of the supply of foreign pyrite, the best of which comes from Spain, and, as a consequence of U-boat patrol of the Mediterranean has not arrived in such large quantities since the German declaration of indiscriminate U-boat warfare, domestic producers have made every effort to increase their output. While the domestic output of pyrite in the first year of the War was less by about 5000 tons than that for the preceding year, the 1914 production having been 336,662 tons, the domestic production of this material in 1915 was the highest on record, reaching the total of 394,124 tons. The 1916 production figures, while not yet available, are understood to show more than a proportionate increase. On the other hand, the imports of pyrite from foreign sources held to an approximate level in 1914 and 1915, but rose last year, as the following figures will show: 1914 (long tons), 977,372; 1915, 974,616; 1916, 1,244,519. Had this proportionate importation continued during the first four months of 1917, the condition of the sulphuric-acid industry would not have been as unfavorable as it is today, but the wholesale sea-raids, and the fear of loss, combined with lack of freight-space, have cut down importations radically, as the import figures for January and February of this year indicate. For these two months there was a decline of almost 94,000 tons, as compared with the corresponding two months in 1916. These being the actual conditions underlying the sulphuric-acid industry, affecting in turn, both the production of munitions and of fertilizing materials, there is ample reason for the serious consideration given the problem, not alone of increased but of stable production of this necessary, by the

Council of National Defense and the advisory bodies collaborating with it in the provision of those commodities essential to the carrying on of an aggressive war and of provisioning this country and the Allies.

THE COUNCIL OF NATIONAL DEFENSE has appointed numerous committees, the chairmen of those related to mining and metallurgical mobilization being as follows: steel, E. H. Gary; aluminum, A. W. Davis; asbestos, magnesite, and roofing, Thomas P. Manville; brass, Charles F. Brooker; coal-tar by-products, W. H. Childs; lead, Clinton N. Crane; mica, L. W. Kingsley; nickel, Ambrose Monell; sulphur, Henry Whiton; zinc, Edgar Palmer. The sub-committee on copper appointed by Bernard M. Baruch, chairman of the Committee on Raw Materials of the National Defense Council's advisory committee, consists of John D. Ryan, president of the Anaconda Copper Mining Co., chairman; Murray Guggenheim of M. Guggenheim's Sons, New York; R. L. Agassiz, president of the Calumet & Hecla Mining Co., Boston; Charles M. MacNeill, president of the Utah Copper Co., New York; James McLean, vice-president of Phelps, Dodge & Co., New York; and W. A. Clark, president of the United Verde Copper Co., New York. This sub-committee will supervise the production by copper mining companies during the period of the War.

THE BUREAU OF MINES rescue and first-aid demonstration car has just started from its base at Reno, Nevada, on its initial itinerary, going first to California, and thence, on May 18, to Grass Valley, on May 27 to Tonopah, then on June 3 to Goldfield, on the 11th to Aurora, and to Ely on the 18th. This is the first of the new all-steel cars completed for the use of the Bureau of Mines. Its personnel consists of Edward Steidle, mining engineer in charge, John V. Berry, foreman miner, Walter F. Pyne, first-aid miner, Donald W. Cooke, clerk. Future itineraries will include the secretaries of the Mine Operators Associations of Utah and California. In case of accident in Nevada, the car can most readily be reached by a telegram to headquarters, at the University of Nevada, at Reno. While in California summons may be sent to H. M. Wolfen, of the California Industrial Accident Commission, San Francisco.

IRON ORE exports from Spain in 1916 were larger than in 1915, despite shipping conditions. The 1916 shipments were 5,148,127 tons, against 4,509,214 tons the year before. Manganese ore exported in 1916 was 6815 tons, as compared with 9136 tons in 1915. Shipments of pyrite were 2,743,487 tons in 1916 and 2,268,223 tons in 1915. It is stated that phosphoric iron ores, which before the War went largely to Germany, have been bought in larger amounts by England and France. Such mines, which closed down after the War, have resumed operation. The inability of the producers of Spanish cupriforous pyrite to ship to the United States at the present time will release considerable quantities for delivery to England, the cinder being available as an iron-ore after extraction of the copper.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

HOUGHTON, MICHIGAN

DEVELOPMENT OF THE CALUMET & HECLA.—A GREAT AND SUCCESSFUL ORGANIZATION.—TAILING ACCUMULATION BETTER THAN A NEW MINE.—EFFECTIVE PATERNALISM.

The development of copper mining in the United States is synonymous with the operation of the Calumet & Hecla mine. It is now 52 years since old man Royale's boarding-house pig stuck his snout into an Indian pit in the back-yard of his road-house and there unearthed a cache of copper. That was practically the beginning of the Calumet & Hecla mine, and for 50 years this great corporation has been taken as the ideal mining investment of the world, for the leadership of all the copper-producing interests, and for 30 years, for the largest production of any of the copper mines of the world.

At the time of the Civil War the world's production of copper was relatively insignificant—the Rio Tinto mines of Spain being at that time the largest producer. The Civil War made a record-price for copper, the metal selling as high as 52 cents for a long time. Michigan was just coming into prominence as a producer of copper, the output being confined to so-called float copper and masses found near the surface. The Quincy mine was then the largest producer. It got out 2,000,000 lb. in one year. The Calumet & Hecla produces that much in three days now. By the way, the Quincy has paid dividends to its shareholders continuously from that time to this, missing only one year (during the Western Federation strike in 1913). A splendid record, surely.

With the discovery of the Calumet conglomerate-lode the whole system of mining copper was changed. It may be well to explain that a lode is an unstratified mineral-bearing vein. The meaning of 'conglomerate' can be found in the dictionary. In this district it is a vein of very hard rock, carrying metallic copper in particles as small as a pin-point up to lumps as large as your fist. The Calumet conglomerate lode has made it possible for the Calumet & Hecla Mining Co. to pay dividends to the shareholders of nearly \$140,000,000, and to pay over \$500,000,000 in wages to thousands of employees and indirectly for maintenance and operation.

In the earlier days of the development of the Calumet & Hecla property the rock was rich. Each year it is becoming leaner. To recover the ore of this lode, miners go down a mile from surface. Then they go from 500 ft. to half a mile from the shaft. The broken ore is put into cars that are trammed to the shaft and dumped into the skips, and hoisted a mile to surface. The rock is dumped and goes through a series of crushing-processes in the shaft-house. It drops into cars, is hauled five or six miles to the stamp-mill, where it is dumped, crushed by stamp-heads having a pressure of five tons, jigged, rolled, washed on numerous tables, re-ground, again crushed, and finally put through an acid process to prevent the escape of the smallest particles of copper. This metal is hauled another mile from the stamp-mill to the smelter, where it is roasted, treated by electrolysis and cast into bars, or slabs, or whatever the customer wants. In this condition it is shipped to New York. All this is done at a cost averaging 10c. per pound for the refined metal. And for every ton of rock that is blasted down in the mine, they get just 20 lb.—1% of copper.

In the early days the rock was richer and it was close to surface. Then they got 100 lb. from every ton, and they lost

30 lb. in the stamp-mill and thought nothing of it. Now they are taking this old stamp-mill tailing and re-concentrating it and it will pay better than a new mine. The fact alone illustrates the progress of copper-concentrating at this wonderful property. With the greater depth, and with the leaner rock, it has been a problem to keep this great corporation up to its standard of earning capacity. The man who took charge of this property when it seemed to be going the way of all mines, was a copper-country product, James MacNaughton, now the first vice-president of the company. His work in the Michigan district today ranks among the greatest industrial achievements of the present generation. Today they are actually doing all this work and getting the rock into the rock-house from a mile

CALUMET & HECLA TAILING DREDGE ON TORCH LAKE

underground at a cost of \$1 per ton. The miners here are the best-paid workmen in the world. Today their average wage is \$5 daily and many of them are cashing contract-checks that run better than \$200 monthly for a period of a year back.

One of the most wonderful things about the Calumet & Hecla company is its paternalism. When we had a strike a few years ago, the only one in the history of the Calumet & Hecla that amounted to anything, the cry of too much paternalism was raised. But it failed, as did the last dying effort of the Moyer-Mahoney gang of Western Federation agitators. This paternalism is not ostentatiously displayed, but it is none the less practical and effective. It gives the Calumet & Hecla the finest class of miners to be found in the world. Recently you saw it announced that the four big copper producers would sell their metal to the Government of the United States for half of the going price. Everybody here believes that suggestion came from the head of the Calumet & Hecla organization.

Last summer the Calumet & Hecla celebrated its golden jubilee. It was a great family gathering. All of the Boston officials, with their families, came to Calumet; everybody took the day off with full pay; there was a parade, the like of which never will be seen again. Gold-medals were presented to every man who had worked for the company 40 years or more, silver-medals were given to those who had worked 30 years, and bronze-medals to those 20 years in the company's service. There were 168 of the gold-medal boys, and they marched at the head of the parade. There was one man who had been

continuously in the employ of the company for 50 years. Tim O'Shea is his name, and he is working every day now. Each of those gold-medals cost \$187.

Last week the announcement was made that the corporation would provide a public park and athletic-field where the celebration took place last summer. The field is in the centre of the town. The best landscape-architect in Boston is going to do the job. It will be a public play-ground. That's just one. The company presented the town with the best library in the State. The late Alexander Agassiz, for years the president and moving spirit in every paternalism of the corporation, presented the school district with a manual-training school, equal to any in the United States. Furthermore, the boys have a ready market for their output, as the Calumet & Hecla pays for anything the company can use. The great amusement-place, ice rink in winter and roller-rink in the fall and spring, and a great meeting place at all times, the Coliseum, is made possible by the Calumet & Hecla's donation of the land, the heat, and the water. Practically all of the married employees of the corporation reside in company houses that rent for one-quarter actual value. They have water free, heat at a ridiculous price in many homes, large yards, pasturage for their cows (and most of them keep their own cows), and dozens of other privileges, such as services of physicians and the best of hospital-service when needed.

This corporation is the greatest of all in the Michigan district and the production is about one-half that turned out in Michigan. The other mines here operate along Calumet & Hecla plans. It is a fine example of a great corporation that has made the mining of copper at a profit one great success, while building up the best class of efficient workmen in the world. And all the while its chief officers have been fighting the greatest industrial battle possible, for this is the lowest-grade copper district in the world—Montana, Arizona, Utah, Nevada—all of them, even the low-grade porphyry properties, mine a grade of ore that actually carries more copper per ton than the average of the Lake Superior district.

JOHANNESBURG, TRANSVAAL

DIAMOND MINING AGAIN ACTIVE AFTER A TEMPORARY SUSPENSION.
—A SYNDICATE FORMED TO CONTROL THE OUTPUT.

Thanks to extensive American purchases the diamond-mining industry of South Africa ought this year to assume pre-war dimensions. In 1915 the total diamond output of the Union of South Africa was valued at £399,810 as against £5,487,194 in 1914. This, however, was only one-half of the normal production, for in 1913 the total value of the diamond output was £11,389,807. Last year, however, the mines gradually began to work again and the total production of diamonds from all sources was 2,346,330 carats valued at £5,728,391. Owing to heavy American buying, it is probable that most of the stocks of diamonds on hand have been disposed of, for while all the mines in the Union of South Africa were closed down as a result of the outbreak of war, they are all now in full work again. One of the results of Mr. Joel's visit to South Africa is seen in the fact that the leading diamond mines have formed a syndicate to regulate the output and selling price of diamonds. The result of such an arrangement is to raise the prices of diamonds, cut down the competition, and thus to enable the leading producing mines to resume mining operations.

At the end of 1916 there were seven diamond mines working in the Union of South Africa of which five were in the Free State, and only one each in the Cape and Transvaal Provinces. These mines produced in the aggregate 2,170,348 carats from the 9,232,322 loads of 16 cu. ft. each washed, the total value of the diamond production being £4,769,479. The Kimberley mines, in the Cape Province, continues to occupy the leading place, and last year produced 1,403,514 carats valued at £3,393,311. The Orange Free State mines produced 218,261 carats worth £723,453, or 66s.4d. per carat as against an average of

48s.4d. per carat for the Kimberley diamonds. The 548,572 carats produced from the Transvaal mine only averaged 23s. 10d. per carat, or a total value of £652,715.

From alluvial washings, as distinct from the rock mines, the production was 167,620 carats, but the average value was 113s. 2d. per carat, of which the bulk came from the Cape Province.

STEMPLE, MONTANA

REHABILITATION OF AN OLD-TIME PRODUCER.—MODERN EQUIPMENT AND UP-TO-DATE METHODS TO REDUCE COSTS.

The Bachelor mine is on the Continental Divide in the old mining camp of Stemple, which is situated 40 miles north of Helena. This mine was worked up to 20 years ago and produced considerable high-grade ore. It was then closed down

THE SIX MEN WHO DROVE 367 FEET OF DRIFT AT THE BACHELOR MINE, IN MARCH

on account of lack of funds to develop more ore. It lay idle until the fall of 1914, when the Royal Exploration Co. took a lease and bond on it, carried on development for six months, then erected a mill, re-built the old abandoned camp and bought the mine.

As the property has been operated by shafts and hoist it was decided to drive a long cross-cut adit and cut the vein 250 ft. deeper. This was completed by the middle of April, and the vein was cut at a depth of 1408 feet.

It is proposed to install an aerial-tram from the mouth of the adit across the canyon to the mill 1300 ft. distant.

By the driving of the new adit and the installation of the aerial-tram, total costs will be decreased 35%.

This district used to be a heavy producer of gold about 20 years ago and it is liable to be revived again by the showing in depth on the Bachelor property.

The ore from the Bachelor vein is free-milling; up to 80% is saved by simple amalgamating. J. A. Wiley is superintendent.

MONTERREY, MEXICO

THE GOVERNMENT ENFORCING THE CARRANZA DECREE OF FORFEITURE ON IDLE MINES.—A REVIVAL OF MINING AND PLANNING EXTENSION OF REDUCTION PLANTS.

According to information that has been received here from Parral and other mining districts in the States of Chihuahua, Durango, and Jalisco, the decree issued by Carranza several months ago, while he was head of the provisional government, and stipulating that unless owners of mining properties in this country resumed operations within a given time their property would be confiscated by the Government, is being enforced in a number of districts. The time of putting into effect this decree was extended twice, the date it finally went into effect being April 1 of this year. It is stated that the local Carranza authorities of a number of mining districts and communities, acting, it is supposed, under the direction or sanction of the Federal Government, have already issued permits or titles to valuable mines that were owned by Americans and others, who have been unable to resume the operation of their respective properties on account of the turbulent internal condition of affairs in the different districts. It is stated in many instances that these local representatives of the Government have turned over rich mines to Mexican laborers and the latter are taking out large quantities of ore and shipping it to the smelter at Torreon.

Practically all of the larger American mining companies in the country have either complied with the Carranza decree, as to the resumption of work upon their properties, or they have been able to obtain an extension of time in which to do so. The confiscatory policy, as it is now being applied, is felt chiefly by the smaller independent mine-owners and the decree is being enforced, it is said, against refugee Mexicans as well as men of other nationalities.

There promises to be a general resumption of mining and smelting operations in Mexico within the next few weeks if the new Constitutional Government, of which Carranza is the head, is able to maintain the existing comparatively peaceful conditions that now prevail in many of the cities and mining districts. The fact that the American Smelting & Refining Co. recently reopened its large plant at Matehuala, in the State of San Luis Potosi, and that it will soon resume the operation of its copper smelter at Aguas Calientes, is looked upon as the beginning of a general revival of the mining industry after a cessation of three or four years. The large smelting plant of the Kansas City Consolidated Smelting & Refining Co., at San Luis Potosi, is also to be reopened within the next few weeks. There is little prospect of the American Smelting & Refining Co. being able soon to reopen its large smelters at Velardeña, in the State of Durango, and at Chihuahua, as bandits are still plundering in those parts of the country.

As soon as it is seen that peaceful conditions of permanency have been established in Mexico, there will be carried out plans for enlarging the copper smelters. It is stated that the capacity of the plant at Aguas Calientes, which now consists of eight furnaces, will probably be doubled. The two smelters in Monterrey, one of which is owned by the American Smelting & Refining Co., are also to be enlarged as soon as the internal conditions of the country justify.

One of the difficulties that first must be overcome in order

that the ore supply for the smelters may be brought up to the requirements when the proposed enlargements are made, is that of providing more adequate transportation facilities. One of the first things on the programme of Carranza's administration, according to advice received here from the City of Mexico, is the re-habilitation of the railroads of the country, particularly those that are necessary to the handling of the ore shipments from the different mining districts. There is a shortage of cars and locomotives, and in view of the war situation in the United States, it is said that it will be practically impossible for orders for rolling-stock to be filled by manufacturers of that country. In order to overcome this obstacle it is proposed by the Government to build large car and machine-shops where the rolling-stock, that is now in such a bad state that it cannot be used to advantage, may be re-built and new cars and locomotives constructed.

It is stated by mining men in the Guanajuato, El Oro, Pachuca, Pueblo, Catorce, and Matehuala districts, as well as in some of the more remote camps of the State of Jalisco and Oaxaca, that there is much activity in the way of mining ores. Many of the mills have been placed in operation after a long period of idleness.

TORONTO, CANADA

SILVER PRODUCTION STIMULATED BY HIGH PRICE.—FLOTATION AT COBALT, WITH POSSIBILITY OF LITIGATION.—EXTENSION OF MILLING PLANTS.—NEW VEINS DISCOVERED IN DEEP WORKINGS.

Activity in silver production has received a great stimulus from the high price of the metal, which has more than counter-balanced the falling off in the grade of the ore at Cobalt. Mining operations are being vigorously pushed and mine-owners are seeking by the adoption of more economical processes and the treating of larger tonnages to offset the lower silver content of the ore. The flotation-process is coming into more general adoption. Mr. Holt, of Salt Lake City, inventor of the Holt-Dern furnace, has been for some time conducting a series of experiments at the Buffalo and Dominion reduction plants on the treatment of flotation-concentrate, with the object of enabling the plants to ship their product in the form of bullion, instead of having to market the concentrate for further treatment elsewhere. It is stated that this experimental work is likely to prove successful. The adoption of the flotation-process, however, threatens to be attended with some legal troubles, as the Dominion Reduction Co. has been notified by Minerals Separation, Ltd., that its further use of oil-flotation in the treatment of ores will be considered an infringement of the patent rights of the Minerals Separation. The decision in the Butte & Superior case may have an important bearing on the proceedings against the Canadian companies. The Cobalt companies having oil-flotation plants in satisfactory operation are the Buffalo, with a mill of 600 tons capacity; Coniagas, 100 tons; McKinley-Darragh, 100 tons; Northern Customs, 100 tons; Dominion Reduction, 200 tons; and National, 75 tons. The Nipissing flotation-plant, of 300 tons, is still in the experimental stage. At the McKinley-Darragh the foundation for an additional flotation-mill of 250 tons capacity is being excavated. The new mill will be of the Marathon type. It is expected to be ready for operation by the end of August. The McKinley-Darragh has discarded stamps in favor of a ball-mill for crushing.

The annual report of the La Rose Consolidated showed a considerably decreased output, the production being 740,065 oz. of the net value of \$449,734. The net profit was \$164,774. Operating cost was 46.39c. per oz. The balance carried forward, after paying dividends, was \$727,169. At the Beaver Consolidated a winze is being put down on the high-grade vein discovered on the 1600-ft. level. The main shaft of the Temiskaming, adjoining, is being put down from the 1600-ft. level to

1800 ft., and exploration at depth is proceeding by cross-cutting. The Peterson Lake has abandoned work at the Nova Scotia shaft and transferred its activities to the property formerly leased by the Susquehanna on the north-west arm of the lake, where a shaft 200 ft. deep has been dewatered and a campaign of exploration will be started.

At the Hollinger Consolidated, every effort is being made not only to maintain, but to increase production, notwithstanding the handicap of inadequate and inefficient labor. The installation of the additional equipment, which will increase the milling capacity by 1000 tons, is expected to be completed in about two months. Underground operations are rapidly increasing the ore reserves. Vein No. 58 at the 425-ft. level is maintaining its width and grade.—The Dome is pursuing a conservative policy and production is slowing down, as the mill is only being worked about two-thirds of the possible running-time. The dividend has been reduced to 10%, the reason assigned being unsatisfactory labor conditions. The agitation among the miners for an increase of 50c. per day continues, but the spirit of restlessness and insubordination among the foreign element, who are chiefly enemy aliens, has been considerably subdued by the action of the Government. A census of this class in the mining districts has been taken and the warning given that if they do not continue steadily at work they are likely to be interned. At the McIntyre great progress has recently been made. The mill is now treating about 500 tons daily, with a yield of about \$10.82 per ton, and large additions have been made to the ore reserves. The drift at the 1000-ft. level is now over 1000 ft. long, the vein showing no falling off either in width or value. The main vein of the North Thompson has been cut at the 600-ft. level where it shows 20 ft. of good ore. The mill is treating 100 tons per day. At the Newray, a new vein, 15 ft. wide, has been cross-cut on the 400-ft. level.

The main vein of the Kirkland Lake has been cross-cut at the 600-ft. level, where it retains the characteristics of the upper levels. The shaft, which is the deepest in the Kirkland Lake district, will be sunk deeper. The Kirkland Midas has uncovered a promising 7-ft. vein. At the La Belle Kirkland 5000 ft. of diamond-drilling has been completed with good results. At a depth of about 700 ft. vertically the main vein was found to be 7 ft. wide, carrying a good grade of milling-ore. Several low-grade veins were cut.

The Canadian government has introduced into Parliament an important amendment to the legislation, imposing a tax on excess business profits. It provides that where annual profits exceed 15% the tax shall be increased 50% on profits over 15%, and where profits exceed 20% the tax shall be 75% on the excess over 20%. As in calculating the profits of mining companies, allowances are made for the exhaustion of ore reserves, it is not considered likely that the mining industry will be seriously affected by the change.

As a result of experimental work now being conducted at the Buffalo & Dominion Reduction Works by the inventor of the Holt-Dern process, the main objection to flotation in Cobalt seems about to be removed. Not only are experiments meeting with success in the treatment of flotation concentrates, for which the process was primarily installed, but it would also appear as though table-concentrate may be treated satisfactorily.

SUTTER CREEK, CALIFORNIA

PROSPECTING FOR OIL IN SACRAMENTO COUNTY.—THE ARGONAUT
NOW THE DEEPEST GOLD MINE IN NORTH AMERICA.—PROGRESS
AT THE OLD EUREKA.

Amador county people, as well as those of Sacramento county, are greatly interested in the oil-drilling about to be

AS THE OLD EUREKA APPEARS TODAY

started at Clay station in the south-east part of Sacramento county, and if the plans of the Laguna Oil Co. materialize, an oil industry may be developed there. The company has recorded leases on nearly 15,000 acres of land in the foot-hill region, and the search for petroleum will begin as soon as the

COTTONWOOD TREES GROWING IN THE OLD EUREKA SHAFT EARLY IN 1916

necessary outfit arrives at Clay. L. Gregor, who has been interested there for several years, secured the leases from the owners. Henry Mitau is president of the Laguna Oil Co., Scott F. Ennis is vice-president, and George W. Peltier is secretary.

The Argonaut mine now has the deepest gold mine in the county, exceeding in the present sinking the Kennedy's depth of 4012 ft. The Argonaut shaft is sunk on an incline; the Kennedy east shaft is vertical, but the Argonaut's present depth of 4667 ft. is equivalent to a vertical depth of 4041 ft., and within a month the Argonaut shaft will be put down an additional 118 ft., making its total depth on the incline 4785 ft., equivalent to 4143 ft. vertical. The encouraging feature in both of these deep mines is that the orebodies continue to maintain their size and value, the management claiming that

their best rock comes from the lowest levels. Twenty stamps of the new Argonaut mill are in operation, also 20 stamps in the old mill, while the other 20 stamps are being moved from the old mill to the new one. It is the intention to have the 60 stamps in operation in the new building within 90 days, when that plant will have a crushing capacity of 300 tons per day. N. S. Kelsey is the superintendent.

At the Old Eureka mine at Sutter Creek, locally known as the Hetty Green mine, work continues as usual. The corporation is known as the Old Eureka Mining Company, capitalized at \$3,000,000. Par value of shares is \$10 each. Issued, 100,000 shares. Incorporated under the laws of Delaware. W. D. Thornton, New York, president; George E. Tener, vice-president; John D. Clarke, New York, secretary; T. Walter Bean, Sutter Creek, general manager.

The depth of the main shaft is 2063 ft. The vein was stoped by the former management from near the surface to the 1800-ft. level, which is the present place of operations.

The mine had been idle for more than 30 years when the present owners began operations. The average dip of the fissure is 71°, and the vein lies at the contact of greenstone hanging and slate foot-wall down to the 1500-ft. level, below which the vein is wholly in the clay-slate.

ALASKA

DEVELOPMENT OF THE MOTHER LODE COPPER MINE PROMISING.— LARGE OREBODIES IN SIGHT.

The new two-compartment shaft of the Mother Lode has been started and is down 51 ft. but has been temporarily stopped awaiting a power-hoist, with a view to developing and opening up the lower ore zone (the zone that all the Bonanza mine workings are on). It is believed that the same conditions will be found on the Mother Lode property. A careful and conservative estimate of the probable ore tonnage and value taken at the present market value of copper and silver indicates the following:

PROBABLE ORE BETWEEN 600 AND 800-FT. LEVELS IN NEW SHAFT

Tons	Copper, %	Silver, oz.	Tons copper	Ounces silver
160,000	15	4	24,000	640,000
80,000	40	10	32,000	800,000
240,000			56,000	1,440,000
Copper value at 30c. per lb.				\$33,600,000
Silver value at 75c. per oz.				1,080,000
				\$34,680,000
Less mining and hoisting charges at \$5 per ton....				1,200,000
Net value at mine.				\$33,480,000

The low-grade ore has been estimated as containing 15% copper and the high-grade as 40%, and while there will undoubtedly be a considerable tonnage running below 15%, so also will there be a large tonnage running over 40 or even 60%, hence these percentages will prove to be a conservative average when the ore is mined.

In the Marvelous workings the average width of the vein is 7 ft., but in the South stope, near the surface, it widened to 18 ft. for a considerable length. In the Pittsburgh North-Drift stope, there is a width of 31 ft. and the eastern wall not yet found. It has been found here that the deeper the workings go the stronger, wider, and richer the vein becomes. The present showing and future outlook of the Mother Lode exceeds anything else ever seen at any previous time since the development commenced, and what was only a good prospect four years ago is now a fully developed copper mine, with a large tonnage of rich ore extracted, blocked out, in sight, and

prospective, as the foregoing figures indicate, and only lacks the mill, power-plant, and wagon-road to make it as great a producer as the Bonanza mine.

CRIPPLE CREEK, COLORADO

DEEPER MINING PRODUCING BETTER RESULTS.—NUMEROUS NEW SHIPPERS.—WATER IN DRAINAGE TUNNEL FALLING OFF.

Deeper development plans are in preparation throughout the entire Cripple Creek district, where many of the principal producers are sinking, and many leasing companies are opening up old producers with this idea in mind. A larger tonnage is predicted from the deeper development of the district for the balance of the year.

Sinking is in progress at the No. 2 shaft of the Portland Gold Mining Co., on Battle mountain, and it will be continued to the same depth as the Cripple Creek deep drainage tunnel. When sinking was resumed the depth of the shaft was 1935 feet.

The Granite Gold Mining Co. also is sinking in the Dillion shaft, with an approximate depth at this time of 1675 feet.

The Excelsior Mining, Milling & Electric Co., operating under lease the Llewellyn shaft, on the Longfellow group of the Stratton Cripple Creek Mining & Development Co., has contracted for the sinking of this shaft from the present depth of 235 ft. to an ultimate depth of 800 feet.

In the vertical shaft of the Modoc Consolidated Mines Co., raises are being cut from the seventh and ninth levels of the Modoc incline shaft, and when the connections have been made the vertical shaft will be several hundred feet deeper than now.

A raise from the 1000-ft. level of the Portland No. 2 shaft will be started after the surveys have been made to connect with the Rose Nichol shaft. The Camp Bird Gold Mining & Development Co. is operating this property under a six-year lease from the Rose Nichol Gold Mining Company.

Lessees Heckler and Denny are sinking a new shaft from surface on the Lucky Corner claim to intersect the Lucky Corner flat-vein at an approximate depth of forty feet. The Lucky Corner claim is owned by the Doctor-Jack Pot Mining Co. and is situated in Squaw gulch.

Sinking will be resumed shortly at the Last Dollar mine, on Bull hill, by the Catherine Gold Mining Co., under direction of Charles Walden, president and general manager. The lower workings were not entered until about May 5 on account of accumulated gas, which was removed by means of fans and compressed air. The bottom level is established at a depth of 1500 feet.

Weir measurements at the portal of the Roosevelt deep drainage tunnel, made last week by Engineer Countryman, recorded the lowest flow since 1915, being 6280 gal. per minute. The heaviest flow recorded, late in 1915 and in the spring of 1916, was 17,000 gal. per minute. Progress of 6½ ft. is made daily with one shift drilling.

The Hahnwald brothers, operating under lease the El Paso Gold King mine in Poverty gulch, commenced shipments this week. Sinking will shortly be started by these operators.

Lessees of the Elkton Consolidated Gold Mining Co. shipped 1000 tons of ore of an average value of \$18 during the month of April. This amount does not include dump-shipments and outside leases, being produced from the main Elkton shaft.

The Trilby mine, operated under leasing plan, is shipping at the rate of a car a week. Von Wald & Co. and E. J. Williams are the only lessees producing ore.

The Beacon Hill properties of the Commonwealth Mining & Milling Co. after a long period of idleness will commence shipments from a new ore-shoot opened up by Carnduff & Duncan, lease operators.

The Cripple Creek district shows some of the effects of the general labor shortage, but with a raise in wages and better conditions prevailing the situation is not one to worry executives. All \$3 men received a raise of 50c. per day, while \$4 men received an increase of 25 cents.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

(Special Correspondence.)—At the Beatson mine of the Kennecott Mining Co. the mill is being enlarged to twice its size, making a capacity of 1500 tons per day. This new unit will be in operation some time the coming summer.

A large amusement hall, including a 'movie' and bowling-alleys on the ground floor, and club-rooms on the second floor, has been completed for the employees. A picture-show is given twice a week and is very popular, since heretofore there has been no amusement of any kind upon the island. The Beatson is employing 350 men.

W. A. Dickey, of Ländlock, has taken an option and lease on the Girdwood property, which has not been worked since 1907 when shipments were made. It adjoins the Beatson mine of the Kennecott company on the north and is supposed to be a continuation of the Beatson orebody. Development consists of tracing the orebody on the surface by open-pits for about 700 ft. along the vein, which on the surface is from 6 to 16 ft. wide and averages 5% copper in a chalcopryite ore. The vein has been tapped at a depth of 245 ft. by a 700-ft. cross-cut adit. Where this adit intersects the vein it was barren, but 50 ft. south, in a drift, ore was found. A stope 50 ft. long was opened up, the vein being 16 ft. thick and averaging 5% copper. On this level considerable work was done south of the stope, but no ore was found. About 100 ft. south of the stope a raise was put through to the surface. Fifty feet above the floor of the stope the vein was opened up by a cross-cut from the raise and found to be about the same in width and value as that in the stope with a little greater length to the shoot. No more ore was found in the raise until within 50 ft. from the surface. The raise came out in the vein on the surface. This would indicate a shoot of ore 50 ft. long and 16 ft. thick in the stope, which appears to extend 50 ft. above the floor as provided by the raise. Mr. Dickey is putting in a wharf, repairing the old tramway and bunkers, and expects to commence shipping ore in July. Under his bond and lease he is obliged to do specified development work in return for the privilege of taking out the ore, and in addition pays Mr. Girdwood a royalty on all ore shipped. He expects to ship from 1000 to 1500 tons per month.

La Touche, May 4.

(Special Correspondence.)—The Granite mine, at Hobo Bay, closed down on May 1. The reason given was the high cost of fuel-oil used for driving the mills and compressors. It is said that the management contemplates the installation of new machinery to obviate the high cost of fuel, but that it is not economical to make such change at this time owing to the high cost of machinery. The Granite is a little gold mine operated by B. F. Millard, and has been running continuously for the last three years. It is equipped with a 10-ft. Lane mill and a 10-stamp mill. From 50 to 75 men are employed.

Port Wells, May 4.

(Special Correspondence.)—The Thomas-Culross property on Culross Island has completed the installation of an 8-ft. Lane mill driven by hydro-electric power and will commence mining and milling within a month. The mine development consists of a 450-ft. adit drift on the vein, gaining 200 ft. of backs at its face. This company is working 20 men.

Culross Island, May 4.

(Special Correspondence.)—Development is progressing on the Daly-Bennett property, an adit having been driven on the vein 400 ft. This vein is an acidic dike from 3 to 4 ft. thick,

and contains little quartz veins at frequent intervals. The quartz carries visible gold. The dike rock itself also carries good value in gold. This property is in charge of B. C. Wiltse and is being financed by Pittsburg people, including Michael Wall, who visited the property recently.

Bettles Bay, May. 4.

(Special Correspondence.)—The Granby Mining Co. is crowding production to the limit of available boat-capacity on the Midas property on Solomon gulch, nine miles from Valdez. They are breaking 200 tons of ore per day, which is shipped to the smelter at Anyox, B. C. It averages about 6% copper.

Valdez, May 4.

The Alaska Mexican Gold Mining Co. reports returns for March as follows: Ran 26 days 1 hour 59 minutes. Crushed 6685 tons, saved 212.34 tons of concentrate. Estimated gross value of concentrate, \$11,888.59. Realizable value, \$11,769.71. Operating expenses, \$10,676.87; estimated operating profit, \$1092.84; construction expenses, \$4308.69; estimated loss, \$3215.85; income from other sources, \$5062.63. Ore yielded \$1.78 per ton. The Mexican mill also crushed 8120 tons of ore from the United company's Ready Bullion mine.

The Alaska United Gold Mining Co. reports for the month of March as follows: Ready Bullion mill ran 30 days 19 hr. 29 min.; by water-power 6 hr.; by electric power, 30 days 13 hr. 29 min. The 700-Ft. Claim mill ran 30 days 12 hr. 39 min. Ore crushed by Ready Bullion mill, 23,905 tons; by Mexican mill, 8120 tons; from Ready Bullion mine, 32,025 tons; from 700-Ft. Claim, 24,675. Concentrate saved: Ready Bullion, 797.09 tons; 700-Ft. Claim, 506.75 tons. Estimated value of free gold saved from 700-Ft. Claim, \$7096.41; estimated value of concentrate from Ready Bullion mine, \$63,073.82; 700-Ft. Claim, \$53,461.12. Realizable value: Ready Bullion, \$62,443.09; 700-Ft. Claim, \$52,926.51. Operating expenses: Ready Bullion, \$48,253.18; 700-Ft. Claim, \$68,223.22. Estimated operating profit: Ready Bullion, \$14,189.91; 700-Ft. Claim (loss), \$15,296.71. Construction expense: Ready Bullion, \$5223.89; 700-Ft. Claim, \$9708.15. Estimated net profit, Ready Bullion, \$8966.02; 700-Ft. Claim (loss), \$25,004.86. Other income, Ready Bullion, \$2040.75; 700-Ft. Claim, \$2040.75. Yield per ton of ore: Ready Bullion, \$197; 700-Ft. Claim, \$217.

The Alaska Treadwell Gold Mining Co. for the month of March reports the following:

The time run by 225 stamps in the 300-stamp mill was 30 days 11 hr. 57 min., running on electric power.

Tons ore crushed	37,828
Tons concentrate saved	785.95
Estimated gross value of free-gold.....	\$ 9,245.03
Estimated gross value of concentrate.....	70,943.18

Estimated gross total production.....	\$80,188.21
Estimated total realizable value	79,386.33
Operating expenses	46,445.29

Estimated operating profit	\$32,941.04
Construction expenses, etc.....	16,641.09

\$16,299.95

Other income	11,838.74
--------------------	-----------

Estimated net profit	\$28,138.69
Yield per ton of ore milled, \$2.12.	

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—There has been more than the usual interest manifested in the Bowie mining district the past month, and a number of prominent mining men and engineers are in this field making examination, with a view either to purchase or to lease. J. W. Sterling, of the Willie Rose Copper Mining Co. of Bowie, made a trip to the Cochise Head property this week with A. D. Mitchell, of Utah. The property comprises a group of 21 claims at the mouth of Wood canyon, south-east of Bowie. The vein is 200 ft. wide, containing disseminated copper glance, in places running as high as 4% copper at the surface.

The Willie Rose mine is closed down temporarily during the installation of a hoist and other machinery. The mine has been shipping high-grade glance ore the past two months; the ore-shoot is in a lime-spar vein 200 ft. wide, and ore down to a depth of 65 ft., has been shipped from it. Machinery is now necessary before again operating. The owners are now considering a proposition to give a lease with an option to purchase the mine.

The Helens Dome Mining Co. of Bowie, is sinking on the cross-fissure of the silver-lead vein on its property, and is breaking some very good ore. J. W. Sterling, of Bowie, has been making a number of examinations in the district and reports having found several good properties, among them the Silver Strike, in Apache pass, which shows a body of silver-lead ore running \$76 per ton. There is a large body of ore, which should prove valuable at the present price of lead and silver.

Bowie, May 12.

MOHAVE COUNTY

(Special Correspondence.)—Operations will be started on the I X L in a few days. The property adjoins the Wrigley Sulphides Company's ground on Stockton hill and has produced a large amount of good ore.

The Minnesota-Connor is to be started up in a short time, New York capitalists having just acquired control of it. The property has much merit and locally it is thought that it only needs intelligent development to make it a producer.

The Gladstone has again been unwatered and is to be placed in operation at once. F. C. Smith and W. B. Twitchell, of the Hidden Treasure, are identified with it.

The power-line is being built to Jessie Knight's Bullion Hill property, though there may be some delay caused by lack of transformers. The machinery for sinking is all in place ready for the electric-current.

San Francisco and Los Angeles mining men have made a 10% payment, of \$6000, on the Silver Hill property and it is considered a certainty that the deal will be consummated.

A. G. Stearns is here from Los Angeles to start work on a second custom-mill, which will be situated on the east side of Silver hill, near the Santa Fe tracks. It will be of 150 tons daily capacity.

The Steffy custom-mill is expected to be in operation before June 15. Nearly all the machinery has been hauled from the railroad to the plant and work is being pushed. The camp will be benefited by this plant early in its career.

The Copper Age mill is nearly ready and is expected to go into operation by the first of June.

The George Washington mine, at Mineral Park, is breaking ground for a mill. A find of rich silver ore is reported from there.

The Puzzle has started a second shaft, which will connect with the bottom of the incline winze in which rich silver ore was recently discovered. The connection will be made at a depth of 100 ft. A hoist is to be placed on this shaft as soon as it can be secured.

The Schuylkill shaft has reached the 800-ft. point and a sump is being cut and cross-cutting will be started for the vein.

If the ore is found as good as expected, a mill will be erected on the property. This company has just purchased a water right from Sam Rhea.

A communication from Swansea indicates that W. A. Clark is planning to build a railroad from that point to connect with his Salt Lake route, passing through Chloride. This would give this district direct rail connection with the Utah smelters.

The 40-ft. shaft on the Bobby Burns is yielding native copper. From three small panfuls of dirt nearly a handful of copper nuggets was recovered. There is a heavy flow of water in the shaft and the extent of the find cannot be determined without further work.

Chloride, May 14.

CALIFORNIA

DEL NORTE COUNTY

Henry Pattison of Crescent City has been permitted to appropriate 3 cu. ft. of Hayden gulch tributary to Hurdy Gurdy creek for mining purposes, by means of a dam 20 ft. high, 30 ft. long on top and 16 ft. at the bottom, to be constructed of timber, rock, and brush.

INYO COUNTY

A permit has been issued by the State Water Commission to Arthur and H. A. Nobles, of Bishop, for 1½ cu. ft. per second of a spring for mining and milling purposes at their tungsten mines. A pipe-line a mile long will conduct the water to place of use at an estimated cost of \$1500.

Charles E. Knox, of Berkeley, has been granted a permit to take 0.04 cu. ft. per second of Burro or Willow springs, and of Rest or Alkali springs, for mining. The works consist of a small concrete dam and a pipe-line 8 miles long.

SHASTA COUNTY

(Special Correspondence.)—The Victor Power & Mining Co. has changed its plant so that it is operated with electricity instead of steam as formerly. For five months of the season the company derives its power from a flume and ditch-line and for the rest of the year a Diesel-engine has been installed to furnish power. The deep Midas shaft is in the process of being unwatered and development has been carried on in the abandoned levels of the mine and some encouraging results have been obtained; experiments with flotation are being made on ore in the dumps of which there is about 700,000 tons with an average value of \$1.50; the value, by screening, can be raised to \$3, and if flotation can be used will make the dumps a valuable asset. Recently an auto-truck was put into service to handle the freight of the company between the property and the railroad 50 miles away. In years gone by the Midas has been a large producer of gold.

Knob, May 16.

(Special Correspondence.)—The 800-acre Menzel ranch, across the Sacramento river and north from Redding, has been acquired by El Oro Dredging Co., of Oroville. Prospecting has been going on for several months with drills, and 100 holes have been sunk to bedrock. It is stated that a large dredge will be built there.

The L. Gardella Dredging Co. is preparing for the building of a second dredge on Clear creek, four miles below Redding, near where No. 1 boat has been operating successfully for a year. It is planned eventually to operate four dredges in this vicinity, as drilling has proved the gold-bearing gravel to be more extensive than originally was anticipated.

The Texas group of 13 quartz claims, near Whitehouse, has been purchased by Robert A. Kinzie and associates, of San Francisco, and orders have been placed for pumps. The old workings are being cleared and it is planned to erect a mill and flotation-plant, as considerable medium-grade ore is exposed.

The Noble Electric Steel Co. has increased the force at its Heroult electric-smelter, and plans to have five furnaces in operation within 30 days. Three will be utilized in the pro-

duction of ferro-chrome, and the two others in making ferro-manganese. It is understood the company has recently secured control of a large manganese property. W. W. Clark is superintendent.

Twenty teams are grading for the \$100,000 flotation-plant to be erected by the Afterthought Copper Co., at Ingot, where materials and equipment are beginning to arrive. An office-building and cottages for employees are under construction, and repairs to the mine workings have been completed. There are 150 men on the pay-roll.

Much new work is going on at the Bully Hill copper mines, and it is reported the management will soon start the erection of a flotation-unit. The ores run high in copper and zinc, with some gold and silver. Developments are principally at the Anchor shaft.

Redding, May 17.

SISKIYOU COUNTY

B. N. Russell, of Weed, has been given a permit to take 3 cu. ft. per second of Dutch creek tributary to Bear creek for placer mining. The work consists of a dam 15 ft. high, 50 ft. long on top and 10 ft. at bottom, of loose rock and timber and a main ditch $3\frac{1}{2}$ miles long. The diversion is near Gottville.

J. W. and H. H. Chapman, J. Ronning, and J. L. Peterson, of Callahan, take 1 cu. ft. per second of Mule creek tributary to east fork of Scott river, for the generation of power for the grinding of ore.

TRINITY COUNTY

The State Water Commission has issued a permit to L. S. Paulsen, of Lewiston, for 30 cu. ft. per second for one diversion and 20 cu. ft. per second for another diversion of Rush creek tributary to Trinity river for hydraulic mining. The main portion of the works is a ditch $6\frac{1}{2}$ miles long. The estimated cost of both diversions is \$7000.

COLORADO

BOULDER COUNTY

(Special Correspondence).—T. E. Shepard has gone to Gordon Gulch where he will have charge of the hoisting-machinery at the Oregon mine.—The U. S. Gold Coin Co., at Sugar Loaf, has resumed development work on its mine.—W. J. Bey and his partner, on Bryan mountain, have found some high-grade tellurium ore, of which a good-sized vein is exposed in the shaft. They soon will put in machinery.—Otto Victor has the most promising silver-lead proposition ever exposed in Boulder county on Tennessee mountain, one and one-half miles below Eldora.—The Up-to-Date mine, at Caribou, is shipping a profitable grade of silver ore.—Emil Schnaeke has a large body of medium-grade ore. A mill is required on this property.—The Dixie mine is getting out some high-grade gold ore.

Eldora, May 14.

PARK COUNTY

(Special Correspondence).—The mining district of Alma derives its name from the town of Alma, which is on the east side of the Mosquito range, nearly opposite Leadville, and is reached by a branch of the Colorado & Southern railroad. Interest in this district dates from before the discovery of gold in California gulch in the Leadville district. Mining operations have been carried on here since the early seventies, though these operations have undergone many vicissitudes. Taken as a whole, the result has been rather disappointing, but in the majority of cases good value in precious metals has been produced, and all indications point to the presence of valuable orebodies still unworked, which may be made profitable with the application of economic methods of mining and treatment.

The chief value of the ore is in its gold and silver content; lead, copper, zinc, and tungsten also are found in paying quantities. There is plenty of vacant ground for the pros-

pector, and many opportunities for capital. Milling and smelting have been carried on here in the past in a small way, and the outlook is good for much activity along these lines this season. At present the camp is laboring under the handicap of a lack of electric-power. For awhile this spring it seemed almost a certainty that the Colorado Power Company would extend its line here from Breckenridge over Hoosier pass, but complications arose which defeated these plans. However, this may be accomplished within the coming year.

The Hockhocking mine and mill have been closed since February 1, but will resume operations within a few weeks. The steam-plant at this property is being replaced by oil-engines of the Fairbanks-Morse type. The mill requires 60 hp., which is divided into four units. Four stamps are used, followed by four Wilfley concentrators, the slime overflow from the double-cone classifiers being treated by a vanner. The tailing from the four Wilfleys is re-ground in a Standard ball-mill. A new Frenier pump is to be used to lift the battery-pulp to the double-cone classifiers. The mill is equipped to handle 35 tons of a lead-iron-zinc ore rich in silver.

The Magnolia mine, on North Star mountain, is under option and lease to L. L. Davis, of Denver. Development of the mine began late last fall and now a good tonnage of mill-ore is in sight. As soon as the weather will permit, the work will be resumed on the tramway from the mine to the old Eddie mill in the gulch near Montgomery. The tram, when completed, will be 4000 ft. long with a capacity of 40 tons of ore in eight hours. The mill has been repaired and is in first-class condition, and will handle 40 tons of ore in 24 hours. The cyanide process will be used, the ore being oxidized quartzite.

The Centennial mine is being worked by J. Elfstrand, and two cars of \$75 ore are ready for shipment as soon as the road is open. A. Lundstrom reports a good showing of ore on the Winona. It is reported that the old Ling mine will be re-opened this summer under company management. The No. 5 adit will be driven ahead from the south side, 400 ft. to connect with the north-side adit at the same level. This tunnel is expected to cut the ore-shoot known to exist below the third level.

Alma, May 14.

SAN JUAN COUNTY

Kramer, Pearson & Giono, who are operating the Congress mine, in Red Mountain district, under lease, during March let a contract for the sinking of a 50-ft. shaft, which was finished by May 1. This gives them a 100-ft. shaft from a 200-ft. cross-cut that was started at the 405-ft. point of the opening shaft, says the *Silverton Miner*.

This new work has opened up a large territory that is rich in mineral and assures sufficient tonnage to keep a full crew busy breaking ore for the remainder of the year.

While working on the 405-ft. level, an immense body of gray copper was discovered. Following this the lessees decided to let a contract for the sinking of the shaft, and when the shaft was down 100 ft. they were in ore. The lessees are now considering letting another contract of 100 ft. either to sink or drive and probably both.

During the winter months the Congress K. P. G., as this lease is known, was one of the heaviest shippers from the Red Mountain district, being credited with a total of about 40 car-loads of ore, some of which is said to have been very rich.

MONTANA

SILVER BOW COUNTY

With an approximate average of 27.9c. per lb. for the copper settlement prices for the month of April, the \$4.75 wage-scale for the next pay-day in the Butte district is assured. The average was so dangerously close to the 27 $\frac{1}{2}$ c. mark, at which the wages automatically drop to \$4.50, that a drop of a cent or two in the copper quotations for any one day might have lowered the scale.

FERGUS COUNTY

At a recent meeting of the board of directors of the Barnes-King Development Co. it was proposed to remove the offices of the company from Kendall to Butte, and to this end the consent of stockholders is being sought, the votes of the holders of two-thirds of the capital stock being necessary for this. The report of the company for the first quarter of the present year shows the following:

Balance, December 31, 1916.....	\$109,120.26
Receipts during first quarter	232,100.65
	<hr/>
	\$341,220.91
Disbursements	\$221,538.92
	<hr/>
Balance, March 31.....	\$119,681.99

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The Jumbo Junior Co. has started development of that part of the Kewanas ground recently taken under lease. The area is 150 by 600 ft. and is being worked from the 880-ft. level of the Jumbo Junior mine. The rich orebody mined in both the Jumbo Extension and Jumbo Junior mines apparently enters Kewanas territory at this point, and some good ore has been already exposed. From its own property the Jumbo Junior Co. is preparing shipments to the Goldfield sampler, hoisting through the Velvet shaft of Jumbo Extension.

The discovery of high-grade ore in the winze from the 600-ft. level of the Laguna mine, of the Goldfield Consolidated, is attracting interest. The winze was sunk in the south-east part of the mine and ore averaging around \$150 per ton in gold and copper was found. This ore is going to the flotation-plant. The Mohawk continues to yield a heavy tonnage of fair-grade material. From the territory recently leased from the Jumbo Extension low-grade copper-gold ore, with occasional seams of high-grade, is being sent to the flotation-plant. The company is again treating approximately 1000 tons of ore daily, divided about equally between the cyanide and flotation-mills.

It is probable that operations will be resumed at the Lone Star in the near future. Control of the company has passed into the hands of Nathaniel H. Wheeler, of New York, and Thomas W. Kendall, formerly with the Goldfield Consolidated, has been appointed resident agent and manager.

The Atlantic company is shipping 300 tons of smelting ore per week, and expects to deliver 100 tons per day to the Garfield Consolidated flotation-plant within a few days. It is officially stated that the orebodies are proving somewhat higher grade than sampling indicated.

Goldfield, May 17.

(Special Correspondence.)—The Jumbo Extension Co., at Goldfield, has resumed work from the Velvet shaft to find the extension of a rich shoot in the Laguna vein. The Goldfield Consolidated recently intersected a rich stringer in a part of the Velvet claim leased from the Jumbo Extension, and is sending a heavy tonnage of flotation-ore from this point to its mill. To reach the extension of the shoot the Jumbo Extension Co. started a raise from near the 700-ft. level, and is also increasing developments on the 790-ft. level of No. 1 shaft. A fair tonnage of good ore is being drawn from the latter workings.—Prospecting with a Calyx drill is proceeding at the Diamondfield Black Butte mine, in the expectation of intersecting the shale-latite contact at a depth of 1000 ft. Any favorable indications will be followed by developments. Several lessees are active, and the Campbell lease is making occasional shipments of \$100 to \$200 ore from the 150-ft. level. Prospecting is being carried on to find the lost Quartzite vein, which yielded over \$500,000 in the early days of the mine.

HUMBOLDT COUNTY

(Special Correspondence.)—The rich shoot opened recently on the 800-ft. level of the Rochester Mines property is improving as work advances. In the hanging wall three more feet of ore has been opened, assays averaging around \$150 per ton. Five drills are operating at this point, which is the deepest working-level in the district. Driving has begun from the 900-ft. level to seek the extension of the rich ore on the level above. Ore showing free gold and native silver has been found in the north drift from the 700-ft. level. The aerial-tramway is in operation, transporting 200 tons daily from mine to mill.

At the Rochester Combined property a 100-hp. compressor, electrically operated, has been added to the equipment, and work has commenced on the Maynaugh tunnel of the Happy Jack group. In the Shepherd group a second cross-cut from No. 1 adit is out 58 ft. and has opened ore of excellent character the entire distance. According to official statements, assays range from 34 oz. silver and \$3.50 gold to 108 oz. silver and \$8 gold. Preparations are being made to start a new adit on the Link No. 1 claim to open at depth the vein disclosed near surface. At the head of the canyon the Christmas adit has tapped the source of the springs, and is supplying 80 gal. of water per minute. This will be used for the mill, for which excavating is proceeding rapidly.

The orebody recently opened on the 100-ft. level of the Bonanza mine of the Winnemucca Mountain Co., near Winnemucca, has been cut at the 200-ft. point, 175 ft. west of the shaft, and is found to carry stephanite and hornsilver. On the 100-ft. level the vein is 21 ft. wide, with a pay-streak of 2 to 4 ft. of rich ore.

The cross-cut from the 800-ft. level of the Seven Troughs mine is out 28 ft. from the shaft and is expected to intersect the vein exposed on the 700-ft. level within 35 ft. Shipping and milling-ore is coming from the No. 2 stope on the 700-ft. level. The last car shipped assayed \$67.50 in gold and \$61.76 silver per ton.

Rochester, May 12.

LANDER COUNTY

(Special Correspondence.)—The Antimony & Silver Mines Co. is installing a 60-ton Denver quartz-mill at its mines near Galene, a short distance from Battle Mountain. The plant includes amalgamating and concentrating equipment and is designed to treat antimony ores, in addition to the gold-silver ores of three different mines controlled by the corporation. In the main property, J. H. Stallings, the manager, states that 1000 tons of gold-silver ore, assaying \$15 to \$40 per ton, is blocked out. A test shipment of antimony ore has been made from a second group, and a large amount of low-grade material is ready for milling.

The Kansas City Consolidated Mining Co. is planning to erect a mill this summer at its property at Bruner, 14 miles from Ione. The mine has a shaft 375 ft. deep. The ore contains gold and silver, and 4000 tons, averaging around \$20 per ton, is ready for treatment. The company has purchased the water rights on Labeau creek, 11 miles from the mine. H. W. Bruner is manager.

Battle Mountain, May 18.

LINCOLN COUNTY

(Special Correspondence.)—An impetus was given to the mining of platinum-palladium ore in the Boss mine and adjacent prospects by a Washington dispatch to the effect that Secretary of Commerce Redfield has instituted a search in the hope of discovering new sources of platinum. It is said that agents of the department have been instructed to make a careful survey of all platinum deposits in Nevada, Australia, Borneo, Tasmania, Russia, Colombia, and other countries. This survey is the third step in the programme to exploit platinum. The first was to conserve all the platinum possible and to make use of platinum that is a by-product of the mints of

the United States. Early in the week it was learned that the secretary had a conference with representative jewelers led by George H. Kunz, of Tiffany's, New York. The secretary requested the jewelers to refrain from the making of jewelry involving a large use of platinum. The second step is to furnish technical assistance in the development of the new platinum deposits in the Boss mineral district near Good-springs, where it has been found practicable to extract the platinum from the ores by a leaching process.

The process referred to is a chloridizing roasting and leaching of the complex Boss ore which contains copper, gold, silver, platinum, and palladium, with some bismuth and other rare metals. Other properties near the Boss that have found similar ore but are still in the prospect stage are the Platino Mines Corporation, the Oro Amigo Platino, and the Scottish Chief group.

Salt Lake capital is showing an active interest in the possibilities of Goodsprings. During the past week, C. B. Stewart and J. B. Jenson, of Salt Lake, purchased the Copper Metals property in Clark Mountain. This property has a 90-ft. shaft, well timbered and equipped with a hoist, and the copper-silver ore on the dump is of good grade.

The Ironsides is at present installing a hoist and straightening its shaft. This mine, which is controlled by Iowa people, has developed a considerable amount of 14 to 20% copper ore.

Vanadium oxide is still found in quantity in the Good-springs Bill Nye mine, one of the steady shippers of 38% zinc ore. Testing of the vanadium ore is being carried on. The Yellow Pine Extension shipped a car of zinc ore last week. Big things are expected of this neighbor of the Yellow Pine, the largest producer of zinc and lead in Nevada.

Frank J. O'Kelly reports that the Frederickson group has been able to increase its output of concentrate by fifty tons per month on account of recent improvements.

R. J. Goodwin, of the Boss mine, has been advised that a large party of Minneapolis capitalists interested in several mines of the district, will make a trip to the district at an early date. It is safe to say that no small mine in America has attracted so much interest from mineralogists and rare-mineral experts as has the Boss. A recent rush shipment of high-grade ore from this mine to the Pacific Platinum Works in Los Angeles assayed 49 oz. gold and 85 oz. combined platinum and palladium. This ore is the plumbo-jarosite, which, according to Adolph Knopf, of the Geological Survey, carries the rare metals.

Goodsprings, May 11.

NEW MEXICO

LUNA COUNTY

(Special Correspondence.)—P. R. Smith, of Deming, and associates, who have incorporated a company with a capital stock of \$1,500,000 to operate the Sanduval Consolidated Copper mines near here, will install a 150-ton flotation concentrating plant and a 35-ton smelter.

The Gymkana Mining Co., of Columbus, will install a concentrating-plant to handle the ore from its mine in the North Peak district.—The Kentucky Mining Development Co. is being organized at Columbus to take over and operate the Kentucky mines situated near that place. Power drilling-equipment and mill will be installed.

Deming, May 14.

SOCORRO COUNTY

(Special Correspondence.)—The Socorro Mining & Milling Co.'s output for last half of April was 1900 lb. gold-silver bullion, making a total for the month in excess of 1½ tons. About 200 tons of ore is treated daily.

The bullion output of Mogollon Mines Co. for same period was 1600 lb., a total of over 1½ tons during April. In addition to the bullion, this company makes regular shipments of concentrate to smelters.

The Oaks Company made another shipment of ore to a custom-mill from the Eberle mine the past week, from development work only. At the Maud S. property the company is now breaking ore in three different places and is sending it to a custom-mill daily, packing the ore by burro-trains.

As the snow is now about off the divide the Mogollon saw-mill is preparing to start for the season and lumber deliveries will begin in a few days.

Mogollon, May 14.

TAOS COUNTY

(Special Correspondence.)—The Buffalo New Mexico Co. is working three shifts in its adit on Pioneer creek. Sixteen men are employed. Richard Kelly is superintendent. Mr. Yunker, of Buffalo, New York, has returned to the East after an inspection of the property.—The Memphis Red River Mining Co. is operating its new oil-flotation mill on Red river, just below town, with satisfactory results. The machinery is operated by water-power.

The Chief Consolidated is driving a development adit on its claims on Goose creek. A large flow of water has been struck.

The El Moro M. & M. Co. is freighting in machinery from Ute Park for an amalgamation and concentration-mill for its property at Anchor, six miles from Red River.

At the property of the Caribel M. & M. Co. the Caribel vein was cut last week 100 ft. above the adit-level. A 60-ft. raise will connect with the upper workings. The vein where cut is of good width and value. The force at this mine will be increased as fast as men are available. There is a marked scarcity of hand-miners here. All work in this camp is being done by hand-drilling, although some of the properties will install machines this year.

Red River, May 12.

OREGON

JACKSON COUNTY

(Special Correspondence.)—H. H. Leonard, who arrived here from Coeur d'Alene last season, is operating the Bowden claims, four miles east of Gold Hill. The mine is owned by J. F. Davis, a local miner, and is situated on the south-east slope of Blackwell hill, near the Pacific highway. Early the present year two mill-tests were made by Leonard from the upper available stopes; 9 tons averaged \$7 in gold per ton, and 16 tons averaged \$8.60 in gold per ton. The ore from this vein has all been free-milling, running from \$7 to \$300 per ton; the concentrate from the two tests referred to assayed \$160 per ton. This vein was first discovered and worked by two ranchers, James McDonough and James Davis, who recovered \$10,000 from \$300 ore from a depth of 50 ft. Since it was first operated the vein has produced about \$30,000, though always mined in a crude manner. The vein is in tonalite, strikes N. 75° E., and dips 85° N. It is from 8 to 30 in. wide, in a 500-ft. drift at a depth of 120 ft. The main shaft west of the original works is 185 ft. deep on the vein, and the 500-ft. drift extends from this shaft. The present lessee has installed steam-power pumps, and hoist, and re-opened the 120-ft. level. He is preparing to join the 120-ft. level west of the main shaft with the other works, and is already down 40 ft. on the new shaft; 30 ft. more will reach the 120-ft. level. A pump with a 2-in. suction readily handles all the water.

Gold Hill, May 14.

(Special Correspondence.)—H. H. McCarthy, an old time mine operator in this district, recently took an option on the North Pole-Lucky Boy group of quartz mines, situated eight miles west of Gold Hill, and south of Rogue river within a mile of the stream. It is owned by Phil Robinson and others living in the district, who discovered the vein six years ago. The lessee is erecting a ball-mill of 15-ton capacity on the property. The mill will be operated by electric-power, which will be available in a short time. A small force of miners is employed in developing for an extensive run on the

ore as soon as the milling equipment is completed. The owners last year shipped three carloads of the ore to the Selby smelter and had five carloads milled at the Opp mill in this valley. All this ore averaged \$28 per ton in gold. The vein strikes due east and dips north at 45°. The vein is from 14 in. to 4 ft. wide. The hanging wall is andesite and the foot-wall is slate. The ore is oxidized near the surface, but at a depth of 50 ft. merges into the base ore. The strike extends up a steep hill sloping toward the river at an angle of 45° with an elevation of 900 ft. at the base, and 2100 ft. at the apex. The principal works on the property is a drift of 175 ft. on the vein at an elevation of 1800 ft., and a drift of 140 ft. on the vein about 1000 ft. below the apex of the hill.

Gold Hill, May 16.

UTAH

Elaborate plans for expansion have been made for the Utah Copper Co. and the other Jackling porphyries as a result of which by mid-year the combined output of the Utah, Ray Consolidated, Chino, and Nevada Consolidated companies should reach a rate of 500,000,000 lb. of copper per annum.

Eventually the two Utah plants will have capacity for handling 50,000 tons of ore per day with the ultimate object of producing 30,000,000 lb. of copper per month.

Ray Consolidated put through its mill last month approximately 10,000 tons of ore daily. This resulted in a March production of more than 8,000,000 lb., a record for any month. This figure should be maintained with ease.

Chino is expected also to produce close to 100,000,000 lb. per year. Its seven-section mill will be able to treat 12,500 tons of ore daily, representing a 40% increase over the present five-section plant. This will not be before the end of the year, however, as the second of two new units cannot be finished for some months, owing to delays in delivery of machinery.

The Nevada Consolidated plant is also being enlarged, but this work will not be completed for several months.

SALT LAKE COUNTY

(Special Correspondence.)—James E. Higgins is working a lease on the property of the Fortuna Mining & Milling Co. at Bingham. The property is owned by Governor Bamberger, and consists of 170 acres and adjoins the Ohio and Utah Copper on the south-east and east. The property has been idle for many years. Since obtaining the lease and option on this property the lessees have shipped 77 cars of high-grade copper ore, and have developed many thousands of tons of low-grade ore. They are now preparing to install a 'K & K' oil-flotation machine of about 100 tons capacity. Recent tests show that a direct saving of from 87 to 96% will be made by oil-flotation. In the mill the operation will be as follows: crush to 65-mesh in a 6-ft. by 16-in. Hardinge ball-mill, the pulp going direct to a K & K machine, using no tables. The ore consists of veinlets of chalcocite in quartzite. The principal vein is known as the Mayflower and is about 35 ft. wide. The average copper content is 1½ to 2½%. Recently 700 tons was shipped to the Garfield plant and the average content was 3.6% copper, 6.5% iron, and 80% silica. The veins all dip under Bingham canyon and therefore under the Utah Copper property. Some interesting developments are expected soon, when the Mayflower and Fortuna veins are opened up at a depth about 1400 ft. deeper than any of the present workings. This will be accomplished through the transportation and drainage adit of the Montana Bingham Consolidated Co. This adit is in 4800 ft. and in the next 300 ft. the Mayflower vein should be cut.

It is not improbable that this development work, after driving on the vein, will open up several million tons of ore, and from present indications another large milling property will be opened in this district. In the testing, as high as 96% of the copper has been floated, the iron dropping with the silica, so that most of the iron will go into the tailing and may be recovered later if advisable.

Bingham, May 13.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

T. A. RICKARD is in Colorado.

L. B. NEWBY has gone to Oregon.

JULES LABARTHE is at Kellogg, Idaho.

CHARLES BUTTERS is leaving for Chile.

ERNEST G. LOCKE is at the Clift hotel.

E. H. NUTTER has returned from Butte.

W. G. SWART is in New York from Duluth.

F. W. BRADLEY has gone to Kellogg, Idaho.

J. H. MACKENZIE has returned from Alaska.

FRANK L. SIZER is at Sutter Creek, California.

LOUIS GOODING was here from Melones, California.

KIRBY THOMAS has returned to New York from Brazil.

B. L. THANE has gone to Vancouver, British Columbia.

WALTER H. ALDRICH will be in San Francisco about June 1.

C. T. GRISWOLD is in Oklahoma, engaged in geological work.

NELSON DICKERMAN has returned from New York and Boston.

H. N. THOMSON has left the United Verde company and is in Los Angeles.

J. E. RASMUSEN was in San Francisco and has gone to Plumas county.

H. E. BUSH is in San Francisco from Taylorsville, Plumas county, California.

J. M. HYDE is not expected to return from Butte before the latter part of June.

GEORGE OTIS SMITH has been appointed a member of the National Research Council.

MARK R. LAMB has returned to New York after several years spent in South America.

G. HOWELL CLEVENGER has been appointed research professor of metallurgy at Stanford.

O. E. ROODHOUSE, superintendent of the United States Tungsten Corporation of Ely, Nevada, is in San Francisco.

FRED H. KAY has resigned as Assistant State Geologist of Illinois to become associated with the Sun Company, of Philadelphia.

V. H. McNUTT has gone from Tulsa, Oklahoma, to Lexington, Kentucky, to investigate the petroleum possibilities of Kentucky.

C. G. VISEL has resigned the superintendency of the Mile Wide Copper Co.'s property and has no further connection with that concern.

A. E. DRUCKER and G. W. LAURIE have opened an office at 30 Church street, New York. The firm will be known as Drucker & Laurie.

FRED B. ELY, M. S. LINDHOLM, and R. C. M. PAGE, mining engineers, are attending the Officers' Reserve Corps training camp at the Presidio.

CHARLES H. LEE, of Los Angeles, has been assigned to duty as an engineer officer of the Officers' Reserve Corps. During his absence his practice will be directed by W. K. BERNARD.

VICTOR C. ALDERSON, JOHN M. BAKER, and HAMILTON W. BAKER have associated themselves as the firm of Alderson, Baker & Baker, at 185 Devonshire street, Boston, with a branch office at Boise, Idaho.

Obituary

C. D. FRASER, treasurer of the Old Eureka Mining Company, and also treasurer of the Hedley Gold Mines Co. of British Columbia, died at his home in New York on May 7.

EDGAR SMART, who is known throughout the metallurgical world as one of the authors of the work on cyaniding gold ores, in which he collaborated with H. Forbes Julian, was murdered by natives in East Africa, in December.

THE METAL MARKET

METAL PRICES

San Francisco, May 22

Antimony, cents per pound	23
Electrolytic copper, cents per pound	33
Pig lead, cents per pound	10.25-11.50
Platinum, soft and hard metal, per ounce	\$105-111
Quicksilver, per flask of 75 lb.	\$95
Spelter, cents per pound	12.00
Tin, cents per pound	20
Zinc-dust, cents per pound	20

For several months past we have published weekly herein the San Francisco market quotations on lead, copper, zinc, and tin, together with some others. Now, however, owing to the unsettled condition of the market and consequent difficulties in obtaining the prices on the four metals above mentioned, we refer those interested to the New York quotations, which we receive by wire each week and which are accurate.

ORE PRICES

San Francisco, May 22

Antimony, 50% metal, per unit	\$1.65
Chrome, 40% and over, f.o.b. cars California, cents per unit	50-55
Magnetite, crude, per ton	\$8.00-12.00
Tungsten, 60% WO ₃ , per unit	20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 45% (under 35% metal not desired), cents, unit	36-38

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese	Per unit \$1.00
46 to 49% metallic manganese	0.98
43 to 46% metallic manganese	0.95
40 to 43% metallic manganese	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

Manganese: The demand for manganese in the East continues strong and the schedule prices remain at \$1 per unit or under; 40% has always found ready buyers at comparatively good prices and the market has a very firm tendency. Chemical ore is quoted at 4½ to 6c. per lb. according to grade.

Tungsten: The tungsten market at New York developed further strength during the past week and absorbed all of the ore of desirable quality. The demand for prompt delivery forced the buyers, for the first time, to accept schedule prices and business has been done repeatedly during the past week at a \$20 basis for 60%, \$21.50 for 65%, with other grades in proportion. There is quite a large demand at the moment of writing, for spot delivery and it has become necessary, in order to meet a 50-ton inquiry, to make up the 50 tons from several small lots. Arrivals from South America expected during this week have been contracted for already with the exception of small quantities and the unsold ore is offered at schedule prices.

EASTERN METAL MARKET

(By wire from New York)

May 22.—Copper is inactive but firm, with prices nominal at 32.50c. Lead is strong at 10.50c. Zinc remains steady and quiet at 9.37c. Platinum is unchanged at \$105 for the soft and \$110 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The circular letter of Samuel Montagu & Co. of April 28 contains the following concerning silver:

The market has shown considerable steadiness at a somewhat higher level. The outstanding feature continues to be the scantiness of the supply, rather than a pressure to buy. The Shanghai exchange has risen in sympathy with the price of silver and sales from that quarter are not reported. Although reports show that there is likely to be an increased activity in the mining industry of Mexico, it does not follow that much silver will come on offer from that country. The details as to Mexican coinage suggest that considerable demands will be made for that purpose upon the local output.

The Indian currency figures recorded below in lacs of rupees show a reduction of 45 lacs in the treasury holding. This is the third successive week that the total has shrunk and is the lowest since February 7 last.

	April 7	April 15	April 23

Tin is abnormally high, the New York quotation being at present around 65c. It was as high as 66.50c. on May 16, going up steadily from 58.50c. at the beginning of the month.

Platinum is quoted at \$105 for soft unalloyed metal and \$110 for the hard natural platinum-iridium alloy.

Molybdenite: There is very little business reported in molybdenite, and prices remain unchanged.

Antimony ore: After a long interval, business has again been done in South American antimony ore at \$2.30 per unit and short ton.

Eastern Metal Market

New York, May 16.

All the metals are decidedly firm, with some much stronger than others. There has been active buying of three of the group, with a dull but firm tendency in the other two.

Copper, while rather dull and inactive, has a firm tendency.

Zinc has remained quiet, but is regarded by no means weak but firm.

Lead is scarce and strong in a fairly active market, good sales being reported.

Tin has had a sensational advance and is higher than in many weeks.

Antimony experienced a decline in the last week, but is again higher and strong.

In the steel market prices continue to soar. Tin-plates have gone at record prices and ship-plates are still without limit, as high as 10.40c. being paid on 1000 tons of hull-plates for Canada. The Government's needs are not yet definite and producers await developments as patiently as possible. It is plain now that the buying of war steel, copper, and other metals, by the Government and the Allies will be done jointly.

COPPER

Not much activity is reported, though some business has been done in third-quarter metal and a little in spot and nearby. In the latter position quotations are conflicting, the metal being scarce this side of July. It is probable that sales of small lots have been made at 31.50 to 32.50c., New York, in the past week. The quotation for early delivery is generally regarded, taking the average of several quotations, as 32c., New York, for both electrolytic and Lake, but it is normal. For third quarter 28.50 to 29.50c. is asked, and business has been reported done at these prices. Some quote 27 to 28c. for the fourth quarter. The market is dull but strong. The underlying strength is due to the belief that consumption is bound to be large for many months to come, especially the needs of the Government and the Allies. Some report that quiet buying is now going on by the Government, while others express skepticism as to this. It is believed, however, that whatever these war needs are and whenever they are bought, they will go at 25 to 27c., New York. The London market was quiet and unchanged yesterday at £142 for spot electrolytic.

TIN

This market has experienced a sensational rise since last week. The metal has advanced almost daily since the last report. Early-delivery tin was selling May 8 at 59.37½c., New York, but on May 9 it advanced to 63c., on May 10 and 11 to 64c., on May 14 to 65c. and was selling yesterday at 65.75c., New York, an advance of over 6c. per lb. in a week. One important cause for this upward movement was the Government proposition of an import tax of 10% on all non-dutiable imports, of course including tin. While indications today are that a revision of this proposed tax will be made before it is a law, the trade will not be surprised if some tax is levied. Another important factor in the advance is the strength of the London market, where the metal in the last week has advanced £21 per ton or from £232 12s.6d. a week ago to £253 yesterday. Nothing definite is known here as to the cause for this unusual rise. Some conjecture that it is due to sunken tin-cargoes while others think that ships may have been withdrawn from the Atlantic service. Early this week, after a few days of comparatively little buying, inquires for about 150 tons of spot and nearby metal appeared which on Monday resulted in sales of perhaps half of this. Some business was also done in tin afloat and for early shipment from London. Yesterday, with less inquiry, heavy sales were reported, totaling 150 to 200 tons, mostly for nearby delivery. Imports of

tin at Pacific points in March are reported at 665,187 lb. at San Francisco and 1,618,079 lb. in Washington. Arrivals in this month to May 15 have been 2680 tons, with the quantity afloat 3597 tons.

LEAD

The statement last week of the *Engineering and Mining Journal* that the Government's requirements for May-June delivery were only 2500 tons tended to release some supplies withheld from the market. As a consequence the metal was not quite as scarce, and a fairly active market developed with good sales recorded. Business in fact was widespread. Late last week May metal sold at 10.25c., St. Louis, with June offered at 10.12½c., St. Louis. Sales in the East were recorded at 10.45 and 10.50c., New York. Most of the cheap lots were wiped out. The quotation yesterday for early delivery was 10.50c., New York. One dealer reports the sale of a carload of lead for delivery as early as possible at 11.62½c., New York. The market is very strong, due to the belief that when the Government's needs are known or satisfied there will not be enough lead to go round.

ZINC

The active market which was expected to follow the announcement last week of the Government purchases of over 10,000 tons of zinc has not materialized. It now develops that only 225 tons of grade C, or prime Western spelter, was included in the purchase, the rest of the amount bought including 6704½ tons of grade A and 3440½ tons of grade B instead. Naturally so small a tonnage of the lower or regular spelter could have but little, if any effect, on the market and the past week has been characterized by little active demand. Sales have been made at the ruling quotations but only for May-June delivery, producers declining to commit themselves as to futures to any extent in so uncertain a market. The market, however, is generally firm and steady, the decision as to Government prices, and the fact that more is yet to be bought, inducing a firm tone. Quotations, at which sales have been made almost daily the past week, are 9.12½ to 9.25c., East St. Louis, or 9.37½ to 9.50c., New York, for May-June delivery. Some quote 9.12½c., St. Louis, for July metal. The attitude of both buyers and sellers is generally a waiting one.

ANTIMONY

The market experienced a further decline since our last report, and metal for early delivery sold at one time as low as 22c., New York, duty paid, due to further arrivals. Since then it has risen again owing to stocks falling into the hands of stronger parties, and the quotation is now 26 to 26.50c. Interest in futures is very strong, May shipment being quoted at 17.50c. in bond and June and July at 16 cents.

ALUMINUM

Buyers and sellers are few and the market is unchanged at 59 to 61c., New York, for No. 1 virgin metal, 98 to 99% pure. The recent export-inquiries are reported to have resulted in no sales. The market is, however, steady but dull.

ORES

TUNGSTEN. Some brokers report no sales of concentrates on the basis of new quotations of \$20 per unit for 60% ore, while others say that the demand has been so strong the past week that business has been done at \$20. Undoubtedly demand is good, and expected arrivals from South America have been contracted for already, according to reports. Ferro-tungsten is unchanged at \$2 to \$2.15 per lb. of contained tungsten.

ANTIMONY. Ore from South America is reported sold at \$2.30 per unit, which is the first business done in a long time, according to the brokers.

Company Reports

MOTHER LODE COPPER MINES COMPANY

The annual report for the year ended December 31, 1916, follows:

During the year the mine was operated 360 days and closed down 5 days—Fourth of July 3 days; Thanksgiving, 1 day; and Christmas, 1 day. Total of 8-hour shifts, as per time-book, 84,904. Average number of men, 28.

MINE DEVELOPMENT AT THE END OF THE YEAR

	Feet
Open-cuts	143
Cross-cuts	1119
Drifts	4272
Raises	1342
Inclines	700
Winzes	179
2-compartment shaft	51
Total	7806

Making the total cutting for the year was 2765 ft., all of which was done by hand-drilling, and showed a gain of 288 ft. over the previous year when power-drills were operated for 38 days.

that the results are exceedingly disappointing. At the time this enterprise was presented to the public it was confidently expected that there would be a profit of approximately 75 cents per ton of ore handled. This profit was estimated on working-cost of 75 cents per ton, and on recovered values of about \$1.50 per ton. The original estimates were based on mill records of an experimental plant operated prior to the acquisition of the property by the company, and the most thorough examination of which such a body of ore is susceptible before its actual mining. The recovered value has been much less per ton than was expected, at the same time the working expenses have fully met the original estimates, despite the large increases in the cost of materials and labor, due to current conditions.

ANACONDA COPPER MINING COMPANY

The annual report of the Anaconda Copper Mining Co. for the year ended December 31, 1906, follows:

During the year the company augmented its holdings by several important purchases. These included the Pilot Butte mine for which \$1,125,000 cash was paid. The east part of the Alex Scott claim was bought for \$750,000.

In addition to these the outstanding interests in the Robert Emmet No. 1, and the Robert Emmet No. 2 claims, lying next to the Gagnon-Original group, were purchased for \$30,598.31. The Raven mining claim was bought for \$63,359.25, and other property in Butte district was acquired at a cost of \$16,231.35.

ORE RESERVES IN SIGHT AND ESTIMATED

	Ore, tons	Copper, %	Silver, oz.	Tons of copper	Ounces of silver
Ore on surface, broken in stopes, and intact above Marvelous level	31,368	15	4	4,705	125,472
Ore between Marvelous level and Pittsburgh level	43,632	15	4	6,544	174,528
Ore between Marvelous level and Pittsburgh level	5,115	30	8	1,534	40,920
Ore between Marvelous level and Pittsburgh level	3,000	60	15	1,800	45,000
Ore between Pittsburgh level and bottom of incline 100 ft.	9,864	15	4	1,479	39,456
Ore on dumps	21,349	8	2	1,708	42,698
	114,328			17,770	468,074

In addition to the above, there is at the lower tramway-terminal, McCarthy railroad depot, and afloat, the following tonnage of ore with its estimated value:

Ore, tons	Copper, %	Silver, oz.	Tons of copper	Ounces of silver
450	60	15	270	6,750
585	30	8	175½	4,680
Copper value at 30c. per lb.				\$267,300.00
Silver value at 75c. per oz.				8,572.50
Total value				\$275,872.50

ALASKA GOLD MINES COMPANY

The fifth annual report of the Alaska Gold Mines Co. for the year ended December 31, 1916, shows the following:

Tons milled	1,892,788
Gross value per ton	\$1.193
Yield	0.970
Tailing	0.222
Extraction, per cent	81.33
Milling cost per ton	\$0.269
Value recovered	0.970
Operating expenses less miscellaneous income	0.732
Total profit per ton	\$0.238

The report of the president says, regarding the above statement: While the foregoing figures show that the business was operated for the year 1916 at a profit, it goes without saying

PROFIT AND LOSS ACCOUNT

Metals in process and on hand at beginning— copper and lead at cost; silver and gold at market	\$18,944,074.67
Mining expenses, including development	24,709,070.58
Ore purchases, including transportation	15,227,457.63
Reduction expenses, including transportation	19,183,022.68
Refining, selling, and transportation	6,760,479.68
Cost of merchandise sold	5,210,178.13

Balance carried down	56,542,338.65
	\$148,190,046.37
Amount charged off this year for depreciation and obsolescence of mining plants, smelters, refineries, etc.	\$7,113,463.00
Interest	951,144.91
Balance, being profit, carried to foregoing bal- ance sheet	50,828,372.29
	\$58,892,980.20
Sales of copper, lead, silver, and gold—that is, deliveries to customers	\$96,097,709.01
Sales of merchandise	7,191,365.94
Royalties, tolls, rentals, etc.	7,675,167.40
Metals in process and on hand at end—in proc- ess, at cost; on hand, sold, at contract prices	37,225,804.02
	\$148,190,046.37

Mining Decisions

MINING PARTNERSHIP—RULE NOT APPLICABLE

A partnership engaged in exploring prospective oil territory is not a "mining partnership," which is defined by California law as existing when two or more who own a mining claim for purposes of working it and extracting the mineral therefrom actually engage in working it, but is a partnership of general scope.

Callahan v. Danziger (California), 163 Pacific, 65. December 27, 1916.

OIL LAND WITHDRAWAL—BURDEN OF PROOF

A withdrawal of land for inclusion in a petroleum reserve based upon an examination and report of its mineral character, establishes prima facie its character as mineral and one seeking thereafter to have it classified as non-mineral assumes the burden of proof to overcome such prima facie established mineral character.

Henry Hildreth (Land Department), 45 Land Decisions, 464. August 31, 1916.

MINING EASEMENT—HELD APPURTENANT

A grant of the right to extract coal and other minerals, together with an easement for the construction and operation of a railroad over which to haul minerals and timber from the land in question, and from other land owned by the grantee, is a grant of an appurtenant easement in the land, and subsequent grantees of the property take it subject to such easement, even though part of the minerals hauled comes from other lands and part of the timber is sold instead of used in the grantee's mining operations.

Jones v. Island Creek Coal Co., (West Virginia), 91 South-eastern, 389. February 6, 1917.

ALASKA COAL LANDS—CONSOLIDATED LOCATIONS

The provision in the Act of May 28, 1908, authorizing the consolidation of coal land locations in the territory of Alaska under certain circumstances, contemplates only such valid and complete locations as had been in good faith made and maintained in accordance with the provisions of the prior existing law of April 28, 1904; and does not operate to validate or cure prior locations which were defective or invalid because of failure to open or improve mines, erect monuments, or to prepare and file notice of location as required by the law in force at that time. Work done merely for prospecting purposes and not with the purpose or design of actually mining and producing coal does not meet the requirements of the statute and does not serve as a basis for a valid location.

Alaska Petroleum & Coal Co. (Land Department), 45 Land Decisions, 56. April 26, 1916.

MINING LEASE—VERBAL SURRENDER

No one will be permitted to acquire and hold mining leases without development where the payment of a royalty upon the ore produced is provided for in the lease. Although it might be conceded that the owner of a mining lease could not assign his rights to a stranger except by an assignment in writing, he could verbally surrender the leasehold to the lessor. If the former partner of such owner, who was required by his contract to give his full time to developing the property, left the State for a number of years and did not communicate with the other partner, his acts constituted a complete abandonment of the partnership, and the remaining partner had the right to surrender the lease without being at all accountable to the former partner.

United Mining Company v. Morton (Kentucky) 192 South-western, 79. March 2, 1917.

Recent Publications

REPORT ON THE PRICE OF GASOLINE IN 1915 BY THE FEDERAL TRADE COMMISSION. Pp. 223 with map and numerous graphic charts. Washington 1917.

In accordance with certain Senate resolutions the Federal Trade Commission is conducting an investigation of the petroleum industry in all its phases. During the latter part of the year 1915 numerous complaints from all parts of the country came to the Commission, charging that the price of gasoline was unreasonably high, and that gross discriminations in price were being practised by refiners and others. These complaints were of such a character and so numerous that the Commission deemed it in the public interest to make a special investigation. This report is the result of that inquiry.

During the year 1915 there were marked changes in the price of gasoline, a fall in prices in the early part of the year being followed by an extraordinary advance. Though varying in different sections of the country, this advance may be roughly dated from July. Taking the wholesale (tank wagon) price as representative, the amount of the advance during the second half of the year was generally between 7 and 9c. per gallon, a rise of from 75 to 85%. In some parts of the country it was more than this; in others less. The advance in retail prices was similar in amount. If the contemporaneous decline in quality of gasoline is considered, the true advance is still greater.

THE FOURTEENTH BIENNIAL REPORT OF THE BUREAU OF MINES, OF COLORADO, FOR THE YEAR 1915-'16. By Fred Carroll, Commissioner. Pp. 116, with maps.

This excellent volume, though small, is concise and filled with valuable information concerning the mineral resources of the State, describing briefly the important mines and mineral deposits in each county. In a pocket at the back of the book are a number of maps of individual counties, which are useful to all who are interested, and it is hoped that similar maps of the other mineral counties of the State will be issued later.

USEFUL MINERALS IN THE UNITED STATES. Compiled by Frank C. Schrader, Ralph W. Stone, and Samuel Sanford. Bulletin No. 624 of the United States Geological Survey. Pp. 412. Being a compilation of the mineral resources of the several States, alphabetically arranged, so that the reader may quickly find the information desired concerning the occurrence of any mineral in any State in the Union. This is a revision of Bulletin No. 585, which is now out of print.

SEVENTEENTH BIENNIAL REPORT OF THE STATE BUREAU OF LABOR STATISTICS OF CALIFORNIA. By John P. McLaughlin, Commissioner, San Francisco. State Printing Office, Sacramento, 1916. Pp. 386.

The volume consists principally of tabulated statements, regarding the labor conditions in California during 1915-16.

ASPHYXIATION FROM BLAST-FURNACE GAS. By Frederick H. Wilcox. Technical paper No. 106, of the United States Bureau of Mines. Ill. with half-tones and line-drawings. Pp. 69. Washington, 1916.

THE RESOURCES OF TENNESSEE. A quarterly review of the conservation and development of the resources of Tennessee. Issued by the State Geological Survey. Nashville. 1917. Pp. 108. Illustrated.

OIL RESOURCES OF BLACK SHALES OF THE EASTERN UNITED STATES. By George H. Ashley. Bulletin No. 641-L, being a part of Contributions to Economic Geology for 1916. Part II. Pp. 22.

CRUDE petroleum coming from Mexican wells is now taxed 10% *ad valorem*, and a minimum value of \$9.50 per ton is fixed by the Government as a basis. Double taxes are also levied upon oil wasted through carelessness or failure to comply with legal regulations. Reports that the Mexican government planned interference with the exportation of petroleum is denied by Ambassador Bonillas on telegraphic instruction from President Carranza. He points out that imposts on oil constitute a chief source of national revenue the suppression of which would be suicidal.

ASSESSMENT WORK on mining claims, held as locators or as part owners by officers and enlisted men in the Army or Navy, will not be required until six months after they shall have been mustered out of the service. This is in accordance with a resolution passed by the Senate, which unquestionably will be confirmed by the House of Representatives. The exemption applies to the heirs of such a claim-owner for a like period after his death. To enjoy this relief from the required annual work, the owner must file in the office in which the original location was recorded a notice of his muster into the service of the United States, and of his desire to hold the mining claim under this resolution.

AGITATION for revision of the Federal mining law had its beginning in a popular belief that the so-called 'law of the apex' was the cause of gross injustice and of extensive wasteful litigation. The amount of the injustice imposed by any provision of a statute would presumably be quite accurately gauged by the number of cases arising under it and becoming matters of court decision. The startling fact that out of a total of 5808 cases arising under the mining law during the last 50 years only 115, or 1.9%, related to disputes over apex rights, is brought out in a scholarly article by Mr. William E. Colby printed in this issue. The other 98.2% of mining cases due to different causes indicate what special committees of the engineering societies have also discovered, that the mining law is not merely weak on a major fault-plane, but that it has been considerably brecciated throughout in the effort at adjustment to the enlarged development of modern mining operations. Mr. Colby has made the most exhaustive study of the law of the apex, in this and in other countries, that has ever been undertaken. He speaks with an authority difficult to contravene, and his conclusions should set at rest the anxiety of those who are ever ready for radical reform. He makes it clear that the situation is not such as to warrant hasty meddling with mining law revision, and

this is especially true while the attention of the country is distracted by a foreign war.

FFUEL economy in reverberatory smelting has been a serious problem in adapting that method to modern requirements in copper metallurgy. Mr. Walter G. Perkins contributes a valuable paper on that subject in this issue, presenting an ingenious application of the regenerative principle to this type of furnace. The attempt is not new, but the practice developed out of the Siemens system, in which the air and gas current was reversed, defeated other necessary objects in copper smelting. The result when using the double-end furnace with the common reversing regenerative chamber is revealed in the failure to secure proper settling of the matte, leaving a slag twice as high in copper-content as is permissible in good reverberatory practice today. Mr. Perkins has proposed a furnace of the accepted form and size in regular practice, with regenerative chambers so arranged that reversal of the air-current through the reverberatory is not required. The details are given in his article, and the results so far obtained in operation are most promising.

JAPAN seizes embarrassing moments to press her demands upon this country for recognition of political privileges that, to speak frankly, could be more readily conceded if her methods were less irritating, and were tintured with more of the graciousness that endears man to man. There was a time, during the Russo-Japanese war, when our people were filled with enthusiasm for Japan and her people; when proper diplomacy and personal decorum might have won her ardently sought 'most favored nation' treatment to the overflowing lip of the chalice. What happened to spoil it all? It would be easy to write the answer. The latest example in the series of unfortunate chills that we have received from that quarter is the choosing of this particular time to press the whole issue of Japanese admission to American citizenship through the case of Takao Ozawa, which is to be heard in the Circuit Court of Appeals in San Francisco next week. This is understood to be a test case, involving a man of wealth and sustained by wealthy Japanese throughout the country. Friendship is not displayed by trying to settle accounts with a neighbor at a time when he is in difficulties.

MAXIM GORKY once left the United States in dudgeon, declaring that there was more personal freedom in Russia. Apparently the Czar erred on the side of generosity. Morris Hillquit and Algernon Lee have also

found that restrictions upon the license of socialistic agitators in the promotion of strife and trouble are consistent with the institutions founded and maintained by a liberty-loving people now once again fighting for the rightful liberties of man. President Wilson has denied them passports to attend the Kaiser's personally conducted international socialistic congress at Stockholm. It is inconceivable that he could have done otherwise in view of the capture of the recent national socialist convention at St. Louis by Teutophile propagandists, who forced the adoption of resolutions that were signed by the parties mentioned denouncing the "declaration of war against Germany" as "a crime against the people of the United States and against the nations of the world," and further declaring that "the acute situation created by war calls for an even more vigorous prosecution of the class struggle," to which is added the pledge of the members to "continuous, active, and public opposition to the war, through demonstrations, mass petitions, and all other means within our power" together with other definite acts intended to hamper and imperil the United States in these days of stress. It is a pity that the same restraint was not made effective against Lincoln Steffens, whose pernicious socialistic influence has now been transferred, at the instance of Senator La Follette, from Mexico to Russia.

Decision on Appeal in the Flotation Litigation

In *Minerals Separation, Limited, v. Miami Copper Company*, on appeal to the United States Circuit Court sitting at Wilmington, Delaware, the majority of the court on May 25 held the first flotation patent (No. 835,120), second patent (No. 962,678), and the third patent (No. 1,099,699), valid and infringed, according to telegraphic advices received. Detailed comment is necessarily withheld until the arrival of the full text of the decision. The majority opinion was written by Circuit Judge Victor B. Woolley, and affirms that the patentability rested upon the critical proportion of oil and the greater and different agitation resulting in a commercial froth. He holds that the agitation claimed under the patent in suit is found first in the centrifugal pump, second in the break in circuit, and third in the Pachuca tank, but, in the opinion of the court, agitation within the scope and meaning of the patent is not found in the Callow cell. This is based on the ground that no experiments were made in court in producing bubbles in tanks or in the Callow cell without previous agitation in a Gabbett mixer, but the decision holds that if the only agitation to which the pulp was subjected, after such agitation as in the prior art was necessary to mix the oil and the ore, was that given in the Callow cells, the court would not say such agitation amounted to or was the equivalent of the patent disclosures, so as to constitute infringement. It is further held, however, that the Miami Copper Company having used the process covered by the patent in the first three steps, this defendant

cannot escape infringement by taking an additional step, even though that step, if taken alone, would avoid the patent. Circuit Judge Joseph Buffington dissented from the verdict, and held that there was no infringement, and that the agitation disclosed in the patent was mechanical, and consequently that aeration is a distinctly different method. It is interesting to note, so rapid is the growth of technical improvement, that even before the hearing in this case had ended the methods of producing agitation to which the verdict relates, had been discarded by the Miami Copper Company, so that the decision is already out of date as regards current practice in flotation. The dissenting opinion should favor the grant of a hearing before the Supreme Court, and the great importance of the issue should result in the Supreme Court admitting a final appeal.

Has the Small Producer a Patriotic Opportunity?

Complaint has been made by an Eastern association of coal miners against the failure of the Government to accord them representation on the sub-committee of the Council of National Defense. Similar criticisms have been made individually in other quarters concerning the absence from the committees on raw materials of persons who might sustain the interests of the great numbers of minor producers. There is justice in that point of view. The committeemen in charge of supplies consist of the leading producers only; the steel committee is made up of Judge E. H. Gary, and Messrs. C. M. Schwab, J. A. Burden, E. A. S. Clarke, A. C. Dinkey, W. L. King, and J. A. Topping, a list that speaks for itself; the copper committee consists of the representatives of the Anaconda, the American Smelting & Refining, the Calumet & Hecla, Utah Copper, Phelps, Dodge & Company, and the United Verde, surely a formidable group. Sulphur is represented by the president of the Union Sulphur Company, nickel by Mr. Ambrose Monell of the International Nickel Company, zinc by Mr. Edgar Palmer, president of the New Jersey Zinc Company, and so on down the list. It is logical and necessary that those who control the bulk of the output should be closely associated with the Government which must know how and where to reach supplies instantly in quantities commensurate with the magnitude of our programme of national defense. Nevertheless, resources of real magnitude in the aggregate are derivable from a multitude of small producers. Narrowing the case down for illustration to the lesser shippers of copper, lead, and zinc ores, it is indubitable that the tendency of the big ore-buyers is to discourage them at the present time. As a result grumbles have become organized into protests, and State politicians have been listening to popular pleas for State smelters, State umpire-assayers, and the like. These suggested remedies we believe to be ineffectual, yet remedies there should be if men can be found wise enough to work them out on a practical basis. It is natural that smelters controlling inde-

pendent resources of ores would prefer to realize upon the reserves in their own mines during a period of high prices, and let the small shipper exhaust his resources and feed the smelters afterward when the ore has a lower market value. This is no more than another instance of the innate unaltruistic Adam, which spirit likewise would move the small miner to apply the same principle for his own pecuniary advantage if he could get the chance. With these fundamental problems of human selfishness we are concerned only so far as relates to the customary governmental forgetfulness of the small fry and the inequities that are permitted to operate against them. One object of a democracy is to be democratic. To pay all regard to the man whose enterprise has made him big enough to be seen above the crowd and forget the others is a bleeding defect in democracy that should receive the attention of the Red Cross corps of the Administration's organization for mobilizing raw materials. Doubtless there is no such corps, but it would be well to take some proper means to insure that the way for the lesser producers to help serve their country in the manner that they know best, which is similar in kind but less in degree than the large producers, is not blocked by these masterful competitors.

A Democratic Bond Issue

The Liberty Loan constitutes a refreshing innovation in democratic finance. Its distinguishing feature lies in the democratic method by which it is being floated. After the Civil War the common reproach hurled at the smug aristocrats who had made money out of Government contracts was that of calling them 'bloated bondholders.' The poor man, the day laborer, the small merchant or farmer, had no chance of getting these desirable bonds. The practice has persisted of offering Government bonds to the highest bidder, in sums and denominations beyond the reach of those possessed of only moderate means. States, counties, and cities almost universally have followed the practice of underwriting bonds through banks and brokers, giving to these a first profit, and restricting the opportunity of the plain people to acquire them in moderate amounts and under favorable conditions. The arguments pro and con need not here be discussed; the prevalent method is sound enough from the standpoint of the financier; it is unquestionably businesslike; but it is not democratic. It helps to define a cleavage between the classes and the masses. The Liberty Loan marks a departure from these undesirable precedents. The man with small savings is given the preference. The bonds are to be sold at their face value, in denominations as low as \$50. They may be registered, or 'bearer bonds' can be selected having interest coupons which will be cashed by any bank as if they were treasury notes. It is even possible to buy them on the installment plan, paying 2% on application and the remainder in certain fixed proportions up to August 30 of the present year. Moreover, allotments are to be made to subscribers for small

amounts even though it be necessary to reduce allotments on applications for larger quantities. Thus the popular character of the loan will be maintained. It is essentially for the people, and the method adopted is in complete harmony with the object of the War it is intended to assist. Its influence is likely to extend into the future, pointing the way to general participation in the financing of public-utility enterprises, thereby helping to strengthen and purify politics, both local and national.

Response to the appeal for subscriptions has been slower than was anticipated, partly because the exceedingly democratic provisions fixed by the Act of Congress authorizing this \$2,000,000,000 issue of Government bonds were not immediately understood, and partly because a false impression that the market would instantly absorb the first issue gained currency from some indiscreet official announcements. The impression was easily obtainable from these earlier comments that the old financial cliques were ready to pounce upon the bonds, leaving the public as usual to pay the bills but get none of the profits. This is contrary to the fact. He who can buy one \$50 bond will be sure to obtain it, while he who subscribes for \$50,000 worth must take pro rata what is available after the small subscribers have been satisfied. The bonds bear interest at the rate of $3\frac{1}{2}\%$, and are exempt from Federal taxes. It is estimated that they are equivalent to ordinary corporate bonds or other investments bearing $6\frac{1}{2}\%$, and their safety is infinitely greater. It is practically the same thing as having money on deposit drawing interest. They will constitute the most liquid asset that one could have in time of stress. Uncle Sam is the most reliable of all debtors; if his credit weakens it will mean that the Nation has been worsted and is at the mercy of a victor, in which case nothing would possess convertible value.

Mining on the Rand

It is a good thing occasionally to see ourselves as others see us, hence the friendly criticism of so intelligent a visitor as Mr. H. Foster Bain ought to be appreciated at Johannesburg. We publish the second part of a long and well considered article by him entitled 'Mining Problems on the Rand.' To those unfamiliar with South Africa the article will convey much interesting information, and it may do something better, by suggesting the application of a similar analysis to their own methods of mining. The Rand is big enough to stand a good deal of criticism. In 1916 the production of gold from this one district, not the whole Transvaal, was worth £38,107,909, which is the highest recorded up to date. During the year the tonnage increased by 210,600, but the so-called working cost advanced 8 pence or 16 cents per ton, the highest since 1907. However, this 'working cost' represents only a fictitious apportionment of the total expense, for while the 'working profit' was £11,630,001, the total of dividends was only £7,095,000. Thus the dividends represent only about 60% of the nominal profit. Similar illusory sta-

tistics are published by the Chamber of Mines. It is curious that the anomaly should be tolerated year after year, rendering ridiculous the otherwise excellent information published by the organization that so efficiently represents a great industry. It is curious that Mr. Bain does not animadvert on this discrepancy between fact and fancy. However, he makes criticisms, possibly of a more useful kind, illustrated by comparisons with large-scale mining in the United States. The comparative regularity of the lode-structure and the relatively homogeneous character of the ore are features that were emphasized more confidently in an earlier decade; the vicissitudes of mining have not been lacking on the Rand, and as the great goldfield becomes old it develops the weaknesses common to age. Nevertheless the seams of gold-bearing banket have given us a type of lode truly remarkable, and the exploitation of them has been conducted on a scale and with an energy such as was undreamed until the Utah Copper and the Chuquicamata set a new standard. The Rand, of course, profited enormously by the financial support given by London, Paris, and Hamburg during the days of its adolescence. The Mexicans say that it requires a gold mine to make a silver mine; it needs capital to develop a low-grade gold mine, and the Rand never lacked capital in the days of its youth. That was due largely to the group of clever and forceful financiers that fathered the plans for deep and extensive mining, when clear-sighted engineers, such as J. S. Curtis, H. C. Perkins, and Hennen Jennings laid them on the board-room table. Those spacious days are over and capital is now less venturesome. Mr. Bain refers to an increase of caution, for mistakes are now less easily retrieved, and mines that are over-bought or over-capitalized cannot be foisted on the public as in the halcyon times when the big fortunes were made. The engineer has come into his own, and technology dominates finance. Mistakes are not so easily covered, the director is reminded that he is a trustee, and the shareholder becomes less timid in asserting his proprietary rights. Mr. Bain discusses some of the vagaries of the London mining market with a gentleness amusing to one better acquainted with the manner in which the working of the mines has been subordinated to share-deals by the 'houses' or 'groups' that control the important companies operating on the Rand. He refers to the way in which an effort was made about ten years ago to achieve a low cost per ton by 'wholesale' mining, that is, by milling an excess of waste, and how the folly of it was so slowly recognized, but not before a series of consolidations, creating super-mines, had enabled the big houses to bury some of their blunders and to get rid of a lot of poor property at the expense of the public. All mining is selective. The purpose of mining is not to create alluring statistics but to make money. Anything that has to be deducted from the yield is part of the cost and the true profit is that part of the yield that reaches the pockets of the shareholders. These are axioms that the big operators and promoters in London and Hamburg buried deeply in sophisticated finance and intricate re-

ports. However, much of that belongs to the past; the question is how to profit by experience and make the most of the remaining resources of this wonderful goldfield. Mr. Bain offers many practical suggestions, based undoubtedly on a discussion of the subject with some of the engineers most familiar with local conditions.

The close saving of the ore, and the redemption of pillars in old workings, are good points. In this work the experience of the coal-miner should prove useful because the conditions on the Rand, as regards dip, walls, and extraction, resemble in many respects those obtaining in coal mining. That is why colliery-engineers have found favor at Johannesburg during the last ten years. Such men ought to be effective there, provided they have had an opportunity to see something of gold mining in other regions before going to South Africa; otherwise they are likely to be too dogmatic. Underground haulage is another important problem. Here the experience of other regions should prove useful, for the last word has yet to be said on this subject. Obviously an exchange of visits between the managers of mines in various parts of the world is the best way of attacking this problem. Insularity is inexcusable in technology, and American engineers are as prone to this defect as others, but not without the excuse that the United States affords a wider range of observation than any other continental area. The Michigan mines used to be antediluvian in their methods, and the Mother Lode region in California likewise has been far behind the times in its technical practice. Self-satisfied conservatism is not peculiar to any one locality, either north or south of the equator. Mr. Bain refers to the custom of keeping a reserve for sweetening the returns, and explains how it was misused—as it was sure to be. The silly custom, with its many deceptions, arose out of the effort to square the speeches of chairmen and directors with the vagaries of ore deposition. The public was asked to believe that mining was an investment, and that the regularity of gold production could be likened to the smoothness of manufactured output. These representations had to be made good by the mine-managers, and the only way to do so was to hold a reserve of gold in the safe, or of amalgam in the mill. By this time the public has learned by bitter experience that uniformity of statistical returns is a delusion and a snare; yet the fiction is still maintained by many companies having headquarters in London, and by some controlled in such centres of enlightenment as Boston and New York. It is time to puncture the fallacy. Ore deposits, particularly those valuable for gold, are subject to variation of composition, necessitating a variable output. The endeavor to maintain a uniform yield entails either juggling with figures or, if it be real, it is obtained at an expense that may well be avoided for the sake of ultimate profit. The result of a mining enterprise should be measured not by the cost per ton or the output per month, nor even the profit per annum, but by the total money divided among the proprietors in a period that enables them to make the most use of that money.

Non-Reversing Regenerative Furnace for Copper Smelting

By WALTER G. PERKINS

It is difficult to give an exact chronological statement of the progress that has been made in the construction of reverberatory furnaces and of reverberatory smelting practice in the last 20 years. It is sufficient to say, in general terms, that the utilization of waste gases began about that long ago and has brought the reverberatory furnace into the field of economics in modern copper metallurgy, whence it has been relegated to second place by the development of the blast-furnace. This development has had many direct and indirect influences on the art, aside from economics alone, as, for example, it has

re-constructing the existing plant. This scheme worked so well that Karl Eilers followed the practice in the construction of the Garfield plant. The next organized radical changes were made by myself in the design of reverberatory furnaces for the Steptoe plant of the Nevada Consolidated Copper Co., where I placed the waste-heat boilers, as shown in Fig. 3. This method has since become practically standard, and has the advantage of giving a better waste-gas distribution to each boiler, as against the tandem method when the first boiler absorbed 60 to 65% and the second was little better than a

DETAIL OF BOILER-SETTINGS AND FIRE-BOXES AS PER CURRENT REVERBERATORY PRACTICE

solved the problem of smelting fine ore and concentrate derived from water concentration and from the flotation process. There were many attempts made to apply the use of the lost heat-units in the waste gases from reverberatory furnaces that constituted from 30 to 50% of the total heat-units produced by the burning of the coal on the furnace grates, by placing steam boilers in the current of the waste gases immediately in front of the throat of the furnace. This was accomplished with considerable success, but the first systematic effort recorded is that by Frank Klepetko at the Washoe plant, where two banks of 50-ft. reverberatory furnaces were built, each with a Sterling boiler attached, placed on the ground at the side of the front of the furnace, as shown in Fig. 1. Later E. P. Mathewson and his staff converted these into furnaces 110 ft. long, with two boilers to each furnace, placed tandem, as shown in Fig. 2, thereby instituting the long-furnace scheme which represents one of the greatest strides in modern copper-smelting practice. The idea of placing boilers tandem was probably suggested by the fact of this being the most convenient method of

water-heater. The later development of the scheme is to take the gases from several furnaces to a common longitudinal flue placed at a right angle to the main axis of the furnaces, and to set the boilers in a battery, drawing the gases to or cutting out any individual boiler as the case may be. I also tackled the fire-box end by changing the construction, which had been carried out in practically all reverberatory-furnace construction from time immemorial, of making a right-angle off-set in the furnace immediately behind the bridge-wall and the conker-plate, as shown in Fig. 4. This limited the width of the fire-box and consequently the amount of grate-area on the width-dimension. I therefore designed the Steptoe furnaces on the lines as shown in Fig. 5.

This method allowed for a fire-box the full interior width of the furnace, with its consequent greater grate-area, and it fully justified itself, as these furnaces have shown that from a standpoint of furnace-capacity the old idea of establishing a necessary ratio of square feet of hearth-area to grate-area has little reason to sustain it, because if the grate-area is large enough to burn enough

fuel properly, there is no necessary limit to the tonnage that can be smelted on any square foot of hearth-area. At that time (1908) the Anaconda plant was smelting about 250 tons of hot calcine, making slag of about 37% SiO_2 , and 40% matte, whereas the Steptoe furnaces smelted 400 tons of hot calcine, making a 45% SiO_2 slag and a 60% matte in furnaces of the same dimensions.

Oil and coal-dust firing have effected great economic changes, but the principle of waste-heat boilers attached to reverberatory furnaces remains the established modern design. The boiler department is a necessity in order to make reverberatory smelting an economic possibility on account of the fact that the reverberatory furnace itself is not economical in its use of fuel and it requires the waste-heat boiler as an auxiliary to use the heat-units that the furnace itself wastes. There is no doubt that, if the many conversations that were held by technical men prior to the time when waste-heat boilers came into general use had been recorded for gramophone entertainment, and these conversations should now be repeated, they would prove interesting and amusing. All ideas are developed slowly, and they not uncommonly result in relegating the 'beaten-track' prophet to the limbo of the past. There are few metallurgists that have been associated with reverberatory work who believe that a boiler plant as an adjunct to a reverberatory-furnace plant is either scientific in principle or entirely satisfactory in operation, and there is no doubt that in the pioneer days many failures ensued before the details of the successful operation of the reverberatory furnace with an attached boiler plant were worked out. Many metallurgists have at some time considered that a reverberatory furnace worked out on the regenerative system would be superior if the inherent problem of keeping the checker-work clean could be solved. No unit in a plant can be termed a scientific accomplishment if it is necessary to have an auxiliary unit attached to it so radically different from the prime unit as are steam boilers in order to make the prime unit an economic possibility, especially when the auxiliary waste-heat boiler-unit has to be worked in a manner which cannot from any point of view be considered good boiler-practice.

Regenerative furnaces that pre-heat the gas and air, and others that heat the air alone, have been used for many years, but nearly all have been of the reversing end-over-end type, as used in steel-practice. The rejection of this type of furnace was primarily because of the clogging of the checker-work with dust going over with the fume; but with the development of the long furnace a metallurgical objection also became an issue in the form of higher slag-losses as shown at Anaconda where long single-end furnaces showed a loss of 0.35% copper as against the Great Falls double-end regenerative type with a loss of about 0.60%, operating under the same metallurgical conditions. The long single-end type does the bulk of its smelting in the first 50 ft. of length from the bridge-wall, thereby allowing the front end of the furnace to take care of a small portion of the smelting, but giving a large quiescent area for allowing the more

complete separation of the small globules of matte from the slag by gravity settling. The double-ended regenerative type of furnace, on the other hand, viewed from a copper-smelting standpoint, is to all intents and purposes two furnaces placed end to end without a dividing wall, and smelting alternately, first on one end and then on the other, and this does not allow any constant quiescent area for the separation of matte from slag. Aside from the two objections enumerated there is one more factor that has exerted an important influence on the development of reverberatory furnaces, and I am not sure that it is not the most important, namely, the plentiful supply of long-flaming coal, rich in volatile constituents, with B.t.u. value of 12,000 to 12,500, such as exists in the Wyoming and Utah coals, used for smelting purposes in Montana, Utah, and eastern Nevada; and the crude-oil supply employed in the Arizona and Nevada smelting plants. These high-grade fuel supplies, coupled with the working out of the use of the waste-gases from reverberatory furnaces, have made it unnecessary to give serious attention to overcoming the difficulties encountered in the proper application of the regenerative principle to reverberatory furnaces for copper smelting in western America up to the present time.

There are, however, two conditions in copper metallurgy where reverberatory smelting even in furnaces with waste-heat boilers attached, is not practicable. The failure may in some cases be entirely economic, as for instance where cheap power from a hydro-electric plant is available, nullifying the value of the waste-gases, thus throwing the entire fuel-expense on the cost of smelting proper, as there are no waste-heat credits to be obtained from the power-plant; or where the available fuel (coal) has a low B.t.u. value, probably combined with physical difficulties which make it impractical to burn it direct on grates or as coal-dust. The latter condition came up in my practice in the Ural mountains, and it was necessary to solve the problem. Reproduced herewith are diagrammatic sketches showing the outline of the furnace and its regenerative chambers, with the flow of the gases and air, a plant that was evolved after much study. The work started with the designing of a large double-ended furnace modified in accordance with modern practice in copper reverberatory-smelting. Later a full set of drawings of the single-end non-reversing furnace was placed in the hands of the Russian operating engineers of the Kyshtim Mining Works, who modified them in some details to suit local conditions and their own ideas, but in the essential features and principles my plans, which are covered by patents, were followed. This furnace has been in operation, although the work has been hampered for want of coal. I visited the plant last summer when they had enough fuel for about a six-weeks campaign, and am able to record that it was a complete success; in fact, I have never seen a reverberatory furnace that carried such an even and continuous temperature throughout its whole length without discharging an impossible quantity of waste-gases. The records are not sufficiently complete to give them in detail, but I can say that I calcu-

lated the metallurgical charge and the fuel used to the basis of American practice, and found that it was equivalent to about 12% on a basis of 12,000 B.t.u. coal and a hot calcine charge. The temperatures in degrees Fahrenheit were: bridge-wall 2732°, throat 2372°, stack 450°, and hot live-air to furnace 900°. The coal that is being used is about 8000 B.t.u. value, low in volatile matter, and with 30% ash. The clinker produced would be impracticable to work on direct-fired furnace-grates, and it causes great difficulty in the producers on account of forming large masses of clinker. The gas produced is of poor quality by virtue of the low volatile content of the coal. From my observation, I think there is little doubt that, with high-grade coal, making a good gas, this furnace would stand a chance of showing better fuel-economy than any combination of furnace with waste-heat boilers attached. This is shown by the low temperature of the stack gas (450° F.), and the high temperature of the live-air coming from the regenerative chambers, which has at times registered as high as 1200° F. I also think that there is obtained probably a greater tonnage-capacity per square foot of hearth-area, as the heat is carried in a more uniform manner throughout the entire length of the furnace without excessive loss of flame at the throat. This latter condition would probably lessen the copper-loss in the slag.

Another factor of importance is that the air and gas can be so controlled that the free oxygen in the waste-gases can be regulated in such manner that either a reducing or oxidizing atmosphere can be maintained in the furnace, which in turn reduces or increases the sulphur-loss by volatilization in the smelting process. This in some plants is an important factor, where the mineral being treated is largely bornite or chalcocite, producing matte of a high grade to the extent of interfering with the economics of the converting operation. This condition would be produced at the expense of fuel-economy in smelting proper, so that the question whether sulphur or coal is of the greater value would have to be determined in each case. The fact, however, remains that this furnace does permit in some degree of the regulation of sulphur-volatilization, which is impracticable in any direct-fired furnace.

In conclusion, it appears to me that the non-reversing regenerative type of furnace has many advantages over any system in which there is used the combination of a furnace with waste-heat boilers attached. The reasons are: (1) it consumes all the recoverable heat-units itself, and is a complete machine, requiring no auxiliary apparatus to make it economical; (2) it allows the construction of the power-plant as a complete unit, on lines conforming to the best practice, creating an economy in the cost of power. The mechanical engineer does and always will consider that having to take steam from reverberatory waste-heat boilers does not give him a chance for good power-practice, although at the present time he has no alternative, as the power-plant must take second place to the reverberatory-furnace section; (3) central or hydro-electric power would become of more

general use if the reverberatory furnaces themselves consumed all the heat-units they produced, leaving the power-factor as an independent unit to be developed along the most economic lines; (4) this furnace can be adapted to coal-dust or to oil-firing, still maintaining the regenerative principle, or it can be used with producer-gas; (5) if the fuel is of high quality the results will be excellent; but even if the fuel is of poor quality, or in fact valueless for any direct-firing system, reverberatory-furnace smelting is still economically feasible, as indicated by the Kyshtim operation, and does not preclude the using of large furnaces and adopting modern metallurgic practice with low resultant costs of smelting.

Platinum in Spain

By F. GILMAN

*Spain has long been noted for its ores of mercury, silver, lead, zinc, copper, iron, and sulphur, and three years ago potassic salts were discovered in the rock-salt district of Cardona in Catalonia. Now the turn of platinum appears to have arrived. In 1913 Domingo de Orueta, a mining engineer and member of the council of the Spanish Geological Institute, during a field-study of the peridotites in the Ronda highlands, in Malaga, became impressed by the analogy between the dunite, harzburgite, and other basic rocks of the district and those of the platiniferous district of the Urals. After a petrological examination of both the Spanish and Russian rocks, Orueta confirmed his surmise. The field of operations was the huge mass of partly serpentized peridotites which extends from near the Mediterranean at Estepona north-east as far as Tolox, a distance of 25 miles, with a width of 8 to 10 miles, rising in several transverse ridges to heights of over 3000 ft. From numerous borings the samples weighing from 30 to 40 kg., were submitted to analysis. The majority proved to be platiniferous, the metal generally appearing in the form of minute, rounded, or flat grains, with a maximum weight of about 2 gm. It is associated with chromite.

The platinum is concentrated in the stream gravels on bedrock and covered by a practically barren overburden from 25 to 30 ft. thick. About one-third of the borings yielded platinum at the rate of 1.5 to 2 gm. per cu. yd., while more than a third contained 20 to 30 gm. The Malaga platinum contains by assay from 78 to 82% Pt, associated with palladium, rhodium, and other rare metals. The original tests were made at Orueta's expense but government aid has now been granted.

SALT-CAKE is sodium sulphate, a by-product from the manufacture of hydrochloric acid. The most common method of making this acid consists in boiling common salt with sulphuric acid in cast-iron kettles. The reaction is: $2\text{NaCl} + \text{H}_2\text{SO}_4 = 2\text{HCl} + \text{Na}_2\text{SO}_4$. The salt-cake contains also some water of crystallization.

*Abstract: Bull. Inst. Min. & Met., April 1917.

Mining Problems on the Rand—II

By H. FOSTER BAIN

The question may fairly be raised whether Rand mining really lends itself to the methods necessary if the full benefit of mammoth units is to be realized. Consideration of the uniformity in character of the ore indicates that so far as milling is concerned there is no difficulty; it will be more a matter of mining and transporting it economically. We must remember that the gold-bearing layers are thin. While there are stopes 15 ft. wide, it is significant that thicknesses are usually stated in inches. W. L. Honnold speaks* of "a rough average of 33 in. which may or may not include quartzite partings." Such a thin orebody will always necessitate a considerable length of cross-cuts, drifts, winzes, and raises per ton mined as compared with the thick, even if irregular, orebodies of other districts; in other words, the ore to be mined is scattered through a wide area. Neither is it continuous or uniformly distributed. That the valuable ore occurs in patches is now generally recognized so far as the Far East Rand is concerned. That it occurs in patches on the Central Rand is also true, although so far the individual patches have proved large and the presence of several parallel ore-beds has both disguised the real distribution and reduced the amount of sinking and cross-cutting necessary per ton, without affecting the amount of driving in banket. According to the report of R. C. Warriner for 1915, only 55.1% of the 6150 ft. driven that year on the reef in the western section of Crown Mines showed ore of profitable grade. In the eastern section, the corresponding figure was 45.3% of 6730 ft. In the East Rand Proprietary the percentage for 1914 was 67, and for 1915 it was 57; taking the Hercules alone, it was 40, and for the whole group to date 45%. It should be remembered that these are deep mines now. Along the outcrop and to considerable depths the ore-shoots were much more continuous along the strike. These figures, however, are not out of line with those in the Far East Rand where the Brakpan, according to Mr. Honnold, showed 50% profitable ground, and Springs for the past year has shown 53. R. N. Kotze, the Government engineer, has taken 40% for a safe average for that district. The steeper dip on the Central Rand increases the tonnage per acre and the total amount easily made tributary to any one shaft, but the fact remains that there is not the same opportunity for centralizing hoisting here that exists in other metal mines.

If, however, analogy be sought in another direction the situation is more hopeful. Many thin coal-beds are worked over large areas, the coal being brought to one central shaft, and, when the mine has been laid out with

that in view, a surprisingly low cost is realized. The actual breaking of coal naturally costs less than in the case of Rand banket, but so long as comparisons are on a tonnage basis it is difficult to see why a bulky material such as coal should be transported and hoisted at less cost than Rand ore. It is also difficult to believe that general costs of ventilation and supervision need be greatly more in a Rand mine, even with its dust, than in a gaseous and dusty colliery. Indeed the analogy is close between the opportunities on the Rand, especially in the Far East where most of the new mines will be opened, and in a modern coal-field. In my judgment the greatest opportunity for further improvement on the Rand is in the underground work and the best chance of success, especially in the Far East where it is to be presumed that most of the new mines will be opened, is through assimilating and adapting coal-mining methods, though perhaps something could be learned from studying the mining of thin-bedded mineral veins such as the Clinton iron ores of the United States. The most striking changes made in recent years in underground practice on the Rand have been introduced from the collieries either by engineers who had had practice in them or by Rand engineers who went to them to study methods. The Consolidated Mines Selection company, in fact, grew out of successful ownership and operation of collieries. At the Lonely Reef mine in Rhodesia excellent points in practice have been introduced from the experience of the Lewis & Marks engineers in coal mining. This brings up the consideration of the third method suggested for meeting the problem of increasingly lower grade of ore, namely, improvement in technical practice above and below ground.

The major operations of mining involve breaking and loading the ore, transporting it to the shaft, and hoisting it to the surface. The first step involves drilling, blasting, shoveling, and takes somewhat different forms as between development-faces and stopes. Incidental to the mining itself there must be subsidiary services designed to protect, ventilate, drain, and illuminate the workings, all of which involve supervision. The rock mined on the Rand is "the hardest on earth." Rand miners and engineers will admit this themselves. Curiously enough "the hardest rock on earth" also occurs in the Lake Superior mines, at Treadwell, Alaska, at various points in Canada, Mexico, Australia, and, in fact, at most of the mines it has been my fortune to visit. At each, unimpeachable local evidence can be brought forward to sustain the claim. Indeed the Rand banket, a thoroughly silicified conglomerate, is hard, but it may be questioned whether it is so hard as to make it out of the question to hope for a higher drilling-speed. Ac-

*Bull. A. I. M. E., August 1915.

cording to figures presented to the Economic Commission by the Chamber of Mines, the average footage per machine-shift is $21\frac{1}{2}$ ft. Allowing 45 minutes per 6-ft. drill-hole it was estimated that the actual average drilling occupied 2 hours and 41 minutes, including the time taken in changing bits. There would seem to be room here for improvement in increasing the effective working-time, also possibly in increasing the speed of drilling. The air-pressure used for drilling on the Rand is about 80 lb. and miners believe that at higher pressure neither drills nor steel would stand up. Drills, of course, can be built for any reasonable pressure and are regularly used at 100 lb. and more in many mines. On the Rand the wings of a bit are subjected to great abrasion, especially in the case of hammer-drills where the action is similar to grinding on a stone. It is not easy to get drills that follow because of quick loss of gauge. The main difficulty with drill-steel is probably due, to an unsuspected degree, to poor or rather irregular blacksmithing, though this is being greatly improved by the use of drill-sharpeners. Loss of drilling-time is in no small measure due to inadequate supplies of steel, poor organization of delivery, and faulty tempering. By close attention to these details, coupled with the use of but one type of drill in the mine and that the water-drill, at Modderfontein Deep, a marked improvement on general practice has been made and while with native labor perfection is not to be expected, improvement may. In an excellent little book called 'Practical Mining on the Rand' and in an article in *The Mining Magazine* of August 1915, E. M. Weston discussed drilling problems in such great detail that little remains to be said. He has also made pertinent suggestions for changes in the work. It seems probable that under Rand conditions improvement in this department can only be expected through patient and unremitting attention to small details and that the gain will be slow. In other words, there does not seem to be any opportunity for revolutionary introduction of machinery or methods such as that of the one-man drill in the Lake Superior copper mines.

In blasting there has already been marked reduction in cost as an incident to the War. Finding it impossible to get materials for making the explosive that had been previously used, substitutes were offered and with slight changes in method of work the new explosive was found to give as good results at less cost. The whole list of stores purchased has received careful study since the War began and in several directions it has been found possible to economize.

In driving a development-face, the cut and the round are often blasted on separate shifts. This is done in order to avoid the necessity for men going through the dust to the face to charge the round after the cut has been blasted. It has the advantage that the remaining holes can be placed to better advantage after the miner sees just what the cut broke, but it has the disadvantage that progress per face is a trifle less than half what the usual plan would allow, and to secure the same develop-

ment there must be a much larger investment in main haulage-ways, deep winzes, and other principal passages. In view of the fact that not more than one drill-shift in 24 hours at a face is permitted in Rand mines the rate of progress, even with normal organization of work, would be slow. It is not to be forgotten that the serious handicap to deep mining is the slow rate of development, having in mind the heavy initial investment in shafts. While development is charged off usually at 2s.6d. per ton, the cost of advance-tonnage prior to milling is about 4s. in the case of deep mines. Even after the mill is erected and in operation the bringing of ore into reserve is disappointingly slow and expensive; and it would perhaps not be too much to say that this is the most critical factor from a technical point of view as regards the future of deep mining. Every effort is made to push development; the slow speed is due in part to the physical conditions and in part to the regulations, which prescribe the manner in which work must be conducted. Any plan that will decrease the footage necessarily held in reserve is worth considering and there would seem to be an opportunity here for the 'delay-action' fuses used in other districts. With them both cut and round can be blasted in sequence without any one going into the dust. The same result can be accomplished, although not so satisfactorily, by cutting fuses to different lengths and firing blast and round at the same time. This is done at some Rand mines. Making it the rule to drill and blast the whole round on a single shift would virtually double the rate of progress at each development-face and so reduce by one-half the number necessary to keep going at one time. It will interest miners in other regions to learn that it is not uncommon for a stope-face to progress only four feet per month. This slow rate of progress entails a heavy overhead cost per ton.

After the rock has been broken in drift or stope, it costs about 2s.2d. per ton to shovel (or 'lash,' as it is locally called) it down the slope, into the boxes, and to haul it to the shaft. In view of the confined space in the workings there is little hope of introducing mechanical shoveling and it is only in special situations that conveyers are economical. In the future mines of the Far East Rand the best plan will doubtless be to convey the trucks direct to the face as is customary in coal mining and as has been described by Mr. Honnold in the article to which reference has already been made.

In stoping, one of the items of expense is the support of the roof. On the Central Rand the roof is so good that it will stand over wide areas for long periods. Indeed the great size of the open stopes is at once a matter of surprise and apprehension to visitors. That the apprehension is not entirely without justification is indicated by the earth-tremors that have become fairly frequent at Johannesburg. These have their origin in the caving of old stopes. Sand-filling is being employed at a number of properties with excellent results and may be expected to become a regular feature of practice in the deep mines where the dip is steep. It is to be regretted that the method was not introduced earlier, for wide

areas of old workings now exist where any general settlement once started cannot be controlled and loss of the remaining part of the mine will probably result. The method of filling with sand has been described in detail by W. A. Caldecott and O. P. Powell.†

In the flat-lying beds of the Far East Rand, sand-filling through bore-holes is not practicable, and in the deeper mines the roof is weak and troublesome. It is held by using 'dry' walls, by 'cribs' of wood filled with waste rock, or by leaving pillars. Each method is expensive and unsatisfactory. Where cribs are built they must cover from one-fourth to one-third of the area of the stope and as the weight comes on them they squeeze down so that they are at best of temporary value. Part, but not all the timber can be recovered when the stope is abandoned. Fortunately the ore over much of the Far East Rand is so distributed that the workable bodies form a series of irregular bodies, which in the Brakpan are so distributed as to form natural panels separated by permanent ribs of barren ground. These ribs are of such size as to preclude danger from a general squeeze. The general plan of operations at the Brakpan is to cut across the course of these oblong patches of ore with the main cross-entries, make rises through them from level to level, and then stope from both sides of the rises to the limits of profitable ore. In the other mines the patches of ore are cut by drifts and winzes as circumstances dictate and then worked outward from these passageways. It is in this last phase of the work that pillars are left or packs built, in the effort to take the ore as clean as possible while the face advances. The question arises whether it would not be more profitable instead to drive from the rise a series of roads laterally to the boundary of the patch of ground to be worked, connect them at the ends, and then work back to the main rise by retreating long-wall methods. Where the roof is favorable this would obviate the necessity for any packs, would use the weight to best advantage in bringing down the rock, and would keep the men under cover. As against advancing work with small pillars it is to be remembered that in coal mining it is a rule that the maximum profit is won from doing the minimum amount of mining on the advance, that is, the most profitable pillar is larger than the one used merely to support the roof. Even under poor roofs it is a question whether more ore might not be mined on the Rand when retreating. The proposed plan would require a larger investment, but it would render the workings safer and it should prove economical. To test the matter would require careful figures based upon actual experience at a particular mine.

Transport of materials underground on the Rand is usually effected for short distances by hand-tramming or trucking. Longer hauls are commonly accomplished by endless ropes, a system that has great vogue in Africa, but electric and petrol locomotives are also in regular use, while experiments are being made with storage-battery locomotives. The advantage in cost seems to be with the rope, where the roads are sufficiently straight to allow its use. Thus at the Geduld rope-haulage costs 9.8d. per ton and at the Modder Deep, with a larger ton-

THE CORNER HOUSE, THE HEADQUARTERS OF THE CENTRAL MINING & INVESTMENT CORPORATION

nage, this comes down to 3.89d. Electric haulage at the Geduld costs 12.057d. per ton but the track is of 18-in. gauge, and crooked, grades are of 1%, and for fear of accidents to workmen the voltage is held down to 240.

It is difficult to get exact comparisons, but the following figures from the Crown Mines are suggestive of the advantage of a system of storage-battery motors for gathering, with delivery to main haulages operated by ropes or electric locomotives.

	Tons	Cost per ton, Pence
Electric locomotive	124,535	2.7
Petrol locomotive	30,911	4.7
Endless rope	25,037	1.9
Storage-battery	13,875	1.4

†Jour. Chem. Met. & Min. Soc., S. A., Sept. 1913.

These figures are suggestive only, as they do not take into account the effects of varying distances and conditions. In discussing the transport of materials with especial reference to work above-ground, C. O. Schmitt* has given much interesting detail regarding rope-haulage and pointed out its limitations.

Having gone to the Rand full of the current idea that it is the field pre-eminently of large-scale mining, it was somewhat of a shock to find the small amount of ore hoisted per day per shaft. It has already been shown that there are only five companies that treat more than 75,000 tons per month and all of these pull from more than one shaft. Nearly half the companies are content with less than 50,000 tons per month and a manager who delivers 60,000 tons per month through two shafts and at the same time handles men and supplies, considers that his record is exceptionally good. This is the more surprising in that the mines are generally dry, they require little timber, and the larger part of the men are underground but one shift. It is true that depths are considerable, but in hoisting it is the starting and stopping that consumes time. Increase in depth does not increase proportionately the time needed to bring a skip to the surface. By way of comparison it may be mentioned that collieries in Great Britain are equipped to hoist 5000 to 6000 tons in two shifts from a depth of 2400 ft. Collieries in Illinois hoist 800 tons per hour from a depth of 700 ft., and it is to be remembered that in colliery practice self-dumping skips cannot be used. The Inspiration Copper Co. in Arizona, using twin shafts, is hoisting 10,000 to 14,000 tons per day of 14 hours from a depth of 630 ft. In this case the hoisting is done automatically by means of 580-hp. direct-current motors, one for each shaft. The engines, having been started, continue to hoist automatically-filled, self-dumping skips until stopped, or until some one of the numerous self-acting safety-mechanisms comes into play. To return to gold mining, it may be mentioned that the new hoisting arrangements at Treadwell in Alaska are designed to handle 5000 tons per day from a depth of 3000 ft. It is not intended to suggest that conditions are the same as on the Rand, but, having in view the great expense of shaft-sinking, too little use is made of a shaft when it is once down. Probably the most striking contrast with Rand hoisting practice is afforded by the Kimberley diamond mines. At the Du Toits Pan 7024 tons was hoisted from 750 ft. in 7 hours 35 min., and at another time 8873 tons in 10 hr. 2 min. At the Wesselton, from 980 ft., 8286 tons was hoisted in 10 hr. 35 min. While methods used elsewhere can hardly be transferred *en bloc* to the Rand, it does seem to be a fair question why Rand engineers do not so change their arrangements underground and at the surface as to permit full advantage to be taken of existing plant and shafts. It is true that most managers start with the mistake already made but there are mines still to be opened and it is a question whether profits would not accrue if some existing shafts were closed. The low rate of hoisting is not

due to poor winding-engines. In the main these are excellent and thoroughly in keeping with the high standard of construction set by the mechanical engineers, but they are not used to capacity. The trouble is with the arrangement underground for gathering the ore and bringing it to the shaft and for this the principal responsibility rests on the men who direct the policy of the mines.

In consequence of using public money in Rand mining, it has become a settled policy to give the industry the greatest possible appearance of stability and regularity. One result is the excellent plan of developing far ahead, so as to create a large reserve of ore. Another is the insistence on uniform monthly returns. It seems to be thought that if the returns went up and down the shareholders would become unduly anxious and that an unhealthy amount of speculation would be induced. The responsible managers also fear that, however honestly they might act, the public would always believe that the grade was being manipulated with a view to the market for shares and that they were making profits out of prior knowledge. There is something in this. It is, however, by no means certain that the shareholders are as concerned about monthly returns as is thought or that, granted that they have become so, it is not largely the result of education. What the shareholders want is dividends and, unfortunately, these have been by no means as regular as the monthly returns of output. However, in practice, the greatest pains are taken to mine to the average of the ore. Formerly this was less closely done and a part only of the gold extracted was declared, the rest being placed in a secret reserve. Then it became the fashion to publish the reserve, after which there was nothing for it but to discard the practice. So that was done—nominally. Actually what happened was that the visible reserve became invisible. It retreated to the amalgam-safes, the zinc-boxes, and the stopes; it is there today and is used regularly to equalize returns. The Rand banket is by no means of uniform value. The grade varies from day to day as in other gold mines. At one mine where I examined the assay-sheets, the ore sent to the mill varied from 4 to 16 dwt. per ton. In two days it jumped from 7 to 16 dwt., and yet the manager must so arrange matters that each month checks with its predecessors at about 6.50 dwt., which is the established grade of the mine. In another property, treating ore averaging a little above 6.5 dwt., there are areas sufficiently large to supply the mill for months at an average of over 30 dwt.

The policy of working to an average grade month by month, necessarily entails keeping open a large number of stopes. It also requires frequent shifting of men and a constant re-arrangement of work underground; in the ore-house it leads to the difficulties of which mention has already been made. Perhaps it is worth the price, but it would be interesting to know exactly what the extra cost is. Approximate estimates made by men on the ground vary from 6 to 12d. per ton. It would seem entirely possible that the cost is even larger if all items be taken with account. There is also the loss of interest due to

*'Rand Metallurgical Practice,' Vol. 2, 1912

rich ore remaining underground. There would be many advantages in adopting the policy of mining the ore as it came, so long as it was above cost in grade. For one thing, the great areas of open ground, left so that it is possible to go back and re-work stopes, are not only a potential danger from possible squeezes, but an actual one in that they interfere with effective ventilation. They are full of dust, which is stirred up by blasting. If an area could be promptly and fully worked, and then filled or closed off, conditions underground could be greatly improved.

As regards ventilation in general, the Rand mines have still a long way to go. A saturated atmosphere and temperatures up to 85° F. are destructive of efficiency, to say nothing of health, among the workers, and there

the air. It is important in all this work to realize that large quantities of air are needed and that it must be carefully directed to the working-places if best results are to follow. Naturally any system of work that reduces the amount of ground open at one time will reduce the ventilation expense. It must be a matter of much careful consideration where to draw the line between the desirable position of having large reserves of varied grade, and of operating with the minimum working cost.

Over a period of years it is impossible to mine faster than ore is developed, and to give reasonable security for investment in plant it is customary to keep in reserve about two years ore-supply, which means loss of interest on the development-cost of that ore throughout the life of the mine to within two years of its abandonment. In

VILLAGE DEEP MINE, SHOWING OLDER TYPE OF PLANT WITH TAILING-WHEEL AND SUPERIMPOSED VATS

are places where such conditions obtain. The mines are just beginning to be systematically ventilated but the companies have not as yet taken ventilation needs into intimate account in laying out underground work. They are about in the stage that the collieries were when they tried to work on a single-entry system, a plan long since abandoned. Having in mind the greater cost of driving in quartzite than in coal, a complete system of double entries seems out of the question, but stoppings, doors, and brattices are not, and with the wide double-track main haulage-ways it might be possible to do something effective by building a thin wall of brick between the two tracks as has been suggested by W. G. Holford.[†] If this were done on the main haulage advancing down the dip, it would be possible to carry fresh air direct to the lowest part of the mine in quantity. This, by decreasing the dust and reducing the temperature, would greatly improve working conditions. For the main laterals the use of a pilot-drift on the ore, connected at intervals with a haulage-drift in the foot-wall, would also carry

the Far East mines, and also probably the deep mines of the Central Rand, the managers feel that development is being pushed at the maximum speed; every face that can be opened is kept going as fast as it can. Where this is true, the critical element is undoubtedly the fact that there is less ore per claim in the deeper ground and that where the dip is flat the amount of driving necessary to develop a ton of ore is greater. It is also much more expensive and difficult to drive at great depth because of the cumulative effect of minor hindrances. While the rate of stoping is slow on the Rand, back of that is the slow rate of development. This can only be improved by changing methods, harder driving, and other alterations which come back to modified regulations. Unless the importance of this be recognized and persistent efforts be made to effect real changes, the cost of mining on the Rand is not likely to be greatly lowered. Concentration in mining must be preceded by intensive development. In this direction the managers realize the need, but between owner, miner, and government they find progress all but blocked.

[†]Trans. Inst. M. & M., Vol. XXIV, p. 278.

In any event, and however far it may prove desirable to push concentration of mining, it is advisable to pay more attention to the main haulages and the shaft-stations so as to get greater returns from the heavy investment in shafts. How large this is and what proportion it forms of the total expenditure is indicated by figures from a number of Far East Rand mines at the end of 1915:

Mine	Shaft-sinking and equipment	Total capital expenditure
Brakpan	£407,976	£1,184,975
Geduld	193,391	1,100,000
Springs	457,497	746,000
Government areas	728,826	1,569,000
Modder B.	131,213	855,159
Modder Deep	131,523	672,000

This problem of possible concentration of work is one that warrants thorough study. On the Rand the ratio of white to colored labor is high as compared with mines elsewhere, and the contract system of directing stoping is proving unduly expensive. If concentration be feasible it is possible that labor difficulties may be lessened by substituting a large measure of direct company supervision for part at least of the contractors, and it is not impossible that the proportion of white to black labor can be made smaller.

In these and many other problems there is a conflict of interest between the engineer striving for technical success and the business manager who must keep in mind immediate as well as ultimate returns. It must also be frankly recognized that a change involves risk to the engineer as well as to the financier. If, for example, it be decided to break the ore as it comes rather than to mine always to grade, the inherent probability of a combination of circumstances leaving the mine with low-grade ore when returns are most needed, must not be overlooked. More money will be made for the shareholders in the end, provided the mine is adequately financed but if it be dependent on the share-market for capital for additional equipment the shareholders might lose as a result of a really sound policy having been followed; in any event, both engineer and manager would need to expect periods of criticism. There is a real conflict here between the claims of technology and financial policy.

It would be presumptuous in a visitor to suggest where in any case the line is best drawn. That is a matter only to be decided after much study and with intimate knowledge of the particular property involved. I would, however, urge the importance of these problems and suggest the advisability of fuller public discussion of them. The opening of the deep mines of the Rand, and particularly those in the central part of the Far East Rand, such as the Brakpan, is a real achievement in mining and this discussion will, I hope, be read more as a frank friendly raising of questions than as a criticism of current practice.

ARSENIC acid is not reduced directly by hydrogen sulphide but gives monosulphoxyarsenic acid ($\text{H}_2\text{AsO}_2\text{S}$) which in the presence of dilute acids gradually breaks down into arsenious acid and sulphur.

New Metallurgical Methods for Quicksilver Ores

For many years California has produced from 70 to 80% of the quicksilver of the United States. This metal is an absolute military necessity, as no substitute for it has been found in the manufacture of fulminating caps. The returns on the production of quicksilver in California for the year 1916 have practically all been received, and show an increase both in quantity and value over the previous year. The total number of flasks (of 75 lb.) amounted to 21,400 and were sold for a total of \$2,000,900 by the mine operators. The quotations varied from \$300 per flask in February to an average of \$75 for the last 6 months of the year. Though the average of quotations for the year was \$125, the actual sales by the producers averaged but \$93.50. Nearly 50% of the above total came from San Benito county, about 20% from Santa Clara county, and the balance from Lake, Napa, San Luis Obispo, Monterey, Solano, and others. The California State Mining Bureau has been investigating the adaptability of water concentration, flotation with oils, and a wet method by solution with an alkaline sulphide in the treatment of mercury ores. Each of these methods has shown some ores particularly amenable to it. High recoveries were obtained by water concentration on tables with some friable ores in which the cinnabar is distinctly crystalline. In ores yielding pulp carrying a cinnabar slime, the extraction by tables is low. The slimed cinnabar can, in many cases, be economically won by flotation when there are no interfering elements in the gangue. Ochre appears to be particularly difficult to overcome, largely on account of its colloidal nature. One interesting development was the verification of information of a selective oil combination for ores carrying large amounts of pyrite. A mixture of crude wood turpentine and a crude asphaltic-base petroleum gave a higher-grade concentrate with less pyrite than any single oil used. In the hydro-metallurgical tests, using a solution of alkaline sulphide (Na_2S and NaOH) some astonishing results were obtained. On four widely different ores, assaying from 0.14 to 1.7% mercury, extractions of 86 to 97% were obtained with approximately a half-hour's contact of the solution on the pulp. On one of these ores, assaying 0.31% mercury, an extraction of 97% resulted after 15 minutes' contact. Ochre, again, is detrimental, if present in excess.

Details of these investigations will be available shortly in a bulletin on California's quicksilver resources, now being prepared by the State Mining Bureau.

LODE LOCATIONS in the counties of Gilpin, Clear Creek, Summit, and Boulder, in Colorado, are limited to 75 ft. on each side of the centre of the vein. In all other counties of the State lode claims may be taken 150 ft. on each side of the centre of the vein. The length is 1500 ft. in every case. The Federal law permits a maximum of 300 ft. on each side of the centre of the vein, and a length of 1500 ft. along the vein.

The Extralateral Right: Shall It Be Abolished?

By WILLIAM E. COLBY

*The Public Land Commission was authorized in 1879 by Act of Congress to investigate all our public land laws and propose a general revision. The Commission advocated the abolition of the extralateral right in its comprehensive report made in 1880. Assuming that it were desirable to abolish the extralateral right, this was the most favorable time to have eliminated it. The Act of 1872 had been in force only 8 years and to have wiped out the law of the apex at that time would have resulted in infinitely less hardship and readjustment than must inevitably follow if that right be abolished after the Act has been in force for nearly half a century. Since this report of the Public Land Commission was issued, the attempt to repeal this feature of the mining law has been urged at intervals. In recent years this sentiment has increased to such a degree, and the abolition of the right is now advocated by so many distinguished mining authorities and leading mining associations, that the subject demands serious consideration. Most of this agitation, however, has thus far been entirely too much engrossed with partisan condemnation of the law of the apex, while but slight consideration has been given to the principles underlying the origin and exercise of the right and those features which furnish some measure of justification for its existence; and practically no thought has been directed to the consequences which must inevitably flow from an outright repeal. These consequences would be exceedingly vital and far reaching and, unless the anti-extralateral advocates can furnish some practical solution which will minimize the mischief, the advocacy by many of them of outright repeal of the extralateral and discovery features of the mining law without a corresponding readjustment of our public land laws all along the line to meet this sweeping change, is going to produce results which will be most detrimental to the mining industry.

It is generally conceded that the fundamental principle of the extralateral right is ideal in theory. The statements of those who have analyzed the situation surrounding the occurrence of lode or vein deposits and who have pointed out the lack of any essential relation between veins or mineral deposits in depth and the overlying surface amply support the principle of severance. All that one has to do is to picture a vein dipping at an angle into the earth and visualize the result of vertical planes passed through surface boundaries cutting off the right to mine on the vein in depth at various points. Take the case where several veins dip either parallel to each other or at varying angles and realize the complex condition that would result if overlying surface-owner-

ship controlled, and vertical planes were projected downward to chop these veins into segments of varying size and at different depths. Then conceive the ideal condition under the extralateral law where the apex-proprietor can follow a certain length of vein down indefinitely on its dip no matter where it leads. The practical result where veins are controlled by surface-ownership and chopped into segments of varying size and at varying depth is to bring about an attempt to consolidate the right to mine on the vein, and thus to sever the underground rights from the surface rights and to make them independent of one another. Only by this means can veins be most economically operated. The intent of the extralateral law was to accomplish this result in the first instance and avoid the necessity of subsequent consolidation, and hence the extralateral law is based on the fundamental conception of economic operation. But, unfortunately, though the extralateral law is ideal in theory, it is far from ideal in practical results. If veins were ideal, with regular width and dip and strike, the extralateral law would work to perfection and no one could seriously advocate change. Veins are, however, so complex in occurrence, with branches, faults, splits, junctions, and every conceivable variation in strike, dip, width, and degree of mineralization, that no matter how well the law of the extralateral right may become settled, disputes will always arise over these physical vagaries.

If we analyze the arguments advanced by those who advocate abolishing the extralateral right, we find that they practically resolve themselves into the objection based on an excessive amount of litigation. It has been assumed by most of these critics without investigation that extralateral litigation is a common occurrence and has become a burden which is seriously hampering the mining industry. Examination of the statistics leads one to believe that the situation has been exaggerated. There has been much expensive litigation, but it must also be borne in mind that, because of the magnitude of the interests involved, such mining cases attract more than their due share of public attention. Taking into consideration the immense importance of the mining industry and the fact that its operations are spread over such a vast territory in the West, the wonder is, not that there are so many extralateral cases, but that there are comparatively so few. Analysis of the law reports and tabulation of all extralateral cases appearing therein shows that during the years 1870-1916 inclusive, in all of the Western States there has been an average of less than three extralateral cases per annum which have been reported. The reported cases do not, of course, include all the extralateral cases which have arisen within this

*Abstract: California Law Review, May 1917.

period, but they do include the more important, and they afford a reliable criterion of the proportion of cases arising from year to year. The maximum was reached in the year 1902 when ten cases were reported. Since 1902 the number of reported cases has steadily decreased so that, for the past decade, excluding duplications of the same case, extralateral litigation has not averaged two reported cases a year. During the years 1908 and 1911 no extralateral cases whatever were reported. The federal extralateral decisions of the trial courts usually find their way into the reports because of their importance. The extralateral decisions in the State trial courts are not found in the reports, but these cases are of such magnitude that they often reach the State appellate courts.

It would hardly seem that the few cases arising in the entire West, especially where an industry of such magnitude and importance as that of lode-mining is involved, would justify the extravagant statements that have been made by some who urge the abolition of the right. It must be remembered that the charge of excessive litigation is the main reason urged for repealing the law of the apex. The deductions of the writer as to the comparatively small amount of extralateral litigation which has arisen, when we consider the vast number of lode-mines being operated in the West under the extralateral law, is corroborated by an independent investigation made by Charles H. Shamel, the author of 'Mining, Mineral and Geological Law.' Proceeding along entirely different lines, he examined the syllabuses of all of the cases reported in Morrison's 'Mining Reports' which contain all the important mining decisions reported in the United States during the past half century. He arrived at the following result: "I confess that I was surprised at the actual figures. The total number of syllabuses in the 22 volumes of decisions is 5808, of which the number concerning the apex law is 115. The apex cases are only about 1.9% of the whole * * * Instead of causing 99.9% of mining litigation, as Dr. Raymond has somewhere stated, it has caused much less than its proportionate share of the trouble. Facts are stubborn things. The chief, the constantly reiterated, the convincing argument, against the apex law is based on a gross mistake as to the facts in the case."

Charles S. Thomas, a United States senator from Colorado, who, as an eminent mining attorney, is well qualified to speak on the subject of mining litigation, corroborates this view. He says: "Now the vast amount of mining controversy—and I am speaking of numbers of actions—has not been apex litigation. They have been the most expensive and the most far reaching. They have perhaps resulted in the greater proportion of injustice; but the conflicting (surface) locations have produced that multitude of cases, a small percentage of which perhaps reach the Court of Appeals, but whose aggregate has burdened the prospector and locator with an expense almost unbearable."

It is not, therefore, an excessive amount of litigation which can be legitimately charged to the extralateral right; the only valid charge on this score which can be

made, is the great expense incident to such few cases as arise.

The advocates of the repeal of the law of the apex have given little consideration to the serious consequences that will inevitably result unless other features of the public-land law are simultaneously and profoundly amended. The greatest practical difficulty that will follow from abolishing the extralateral right and confining a locator to the mineral found within the vertical boundaries of his location, is the fact that only in those locations which embrace the apex of the vein can a discovery of mineral readily be made. Discovery of mineral within the boundaries of the location is the most vital essential of our existing mining law. Locations which include the apices or upper portions of the veins within their boundaries could still readily meet this important requirement of discovery, but surface locations overlying the dip of the vein at considerable distances from the apices, or upper terminal edges, of the veins could meet the discovery requirement only after the locators had expended considerable labor and time in sinking shafts to find the vein in depth. As the vein dipped farther into the earth it would be increasingly difficult to make a discovery within the vertical boundaries of the overlying locations, and finally at great depth the expense of sinking such shafts would be prohibitive. It would be necessary under existing discovery-requirements to sink vertical shafts on each surface location in order to perfect a discovery on each claim, and there would be a consequent economic waste resulting from the expense of unnecessary duplication of such shafts. Under the extralateral law as it now exists a discovery on the apex of the vein is sufficient, and the vein may be developed to great depth by a single shaft advantageously situated.

The consistent advocates of the abolition of the extralateral right cheerfully concede that this practical difficulty is serious, and they are therefore forced to urge that the discovery-requirement of the mining law be abolished also. If these two fundamental features—discovery and extralateral right—are eliminated, the system of American mining law built up as a result of years of experience and intelligence of practical pioneer miners will have been virtually emasculated. Little more than an empty shell will remain. Many critics have stated that the discovery-requirement is a feature characteristic of American mining law exclusively, and that it is a useless requirement, unnecessarily suffered by the American miner. Both statements are erroneous. The discovery-requirement is characteristic of most of the systems of mining law in the world. The elimination of the discovery feature from our law would wipe out the simplest and most practical form of test as to whether land is mineral or not.† Such elimination would destroy the simple test whereby mineral lands are now practically and easily classified under existing law so that mineral locators are able readily to defeat agricultural claimants desiring to obtain the same lands. The alternative test would be to

†Revision of the Mining Law: Discovery, M. & S. P., February 7, 1914.

leave such classification to an appropriate branch of the Federal Government. Even this alternative would be open to serious objection. It would substitute the opinion of mineral experts and representatives of the Federal Government as to mineral character of land in place of the views of the practical miner; it would mean aggravating delays where mines were discovered in rugged or desert regions remote from centres of travel; it would overturn a fundamental principle embodied in our mining laws by the pioneer miners, a principle which was the heritage of ages of mining experience and finally it would tear down and destroy to a large extent the great body of law that has gradually been developed with infinite patience and practical wisdom as a result of judicial interpretation operating through more than half a century. The law of discovery is now well settled and understood and to substitute for it an unknown and untried quantity would mean another period of uncertainty and litigation until a similar line of interpretative decisions had been rendered with respect to the new law. This superstructure of judicial interpretation is as important a part of the law, and is as necessary for its satisfactory working as is the organic law which it interprets. It is even more important in one sense, for the organic law may be created overnight as it were, while the interpretation and harmonizing of it, especially in its relation to other laws, takes years to accomplish.

Another practical difficulty to which the elimination of the extralateral right will give rise is that in certain of the Western States condemnation of private rights of way for mining purposes is not permissible. The courts of these States have not taken the broader view followed in other States where it is held that the public welfare is so dependent upon the mining industry that a private mining operator can exercise the right of condemnation for rights of way for mining purposes. The practical effect of the abolition of the extralateral right in those States which deny the miner such a right of condemnation would be to render him unable to operate as one mine two separated segments of the vein underlying two separated parcels of surface land where the intervening surface-owner objected. Under existing extralateral law he has the right to follow his vein on its dip irrespective of surface ownership overlying the dip. Another consequence of the elimination of the extralateral right would be to make the ownership of overlying surface all important. Under existing law the extralateral claimant frequently is willing to make a material concession to his neighbor when it comes to a dispute as to the ownership of surface on a portion of his claim. If the surface in controversy does not include any portion of the apex of the vein, the surface right frequently does not assume sufficient importance to justify litigation, and controversies are usually amicably settled, or the surface proprietor is bought out for a comparatively small sum. If the right to the vein should become entirely dependent upon surface ownership, it is obvious that surface title becomes so vital that disputes over surface would increase in number and be contested more bitterly than in the

past. Practically all of the States of the West have also legislated on the subject of mining law, supplementing the laws of Congress. Most of these have embodied in their legislation the extralateral provisions of the federal statutes. While action by Congress abolishing the extralateral right would doubtless have the effect of rendering these State statutes inoperative, yet it would become necessary for each State to wipe this legislation off its statute books and harmonize its laws with the enactments Congress might see fit to substitute therefor.

These obstacles are not insuperable, but attention is called to them for the purpose of showing that the repeal of the extralateral law would be attended by far-reaching results.

Unfortunately, we cannot start anew, and we are confronted with the practical situation that during the past 67 years there have been thousands of claims located and patented under the law granting extralateral privileges with which we must reckon, for it is inconceivable that any rights already vested will be destroyed.

Two fundamentally opposed systems of mining law operating side by side, one based on the principle of severance of mineral from the surface and the other based on surface ownership carrying with it the right to everything vertically beneath, would not tend to simplification, but would inevitably add an increasing number of problems to be litigated in the courts.

The situation can be met in another way. In each State there should be a provision added to its laws whereby a judge, specially qualified to try extralateral cases, could be called in to sit where such rights are involved. To the average judge an extralateral suit is like so much Greek, and a large portion of the trial is taken up with educating the court on the elementary principles involved. In practically all foreign countries a special tribunal is established to try mining cases, and in some countries jurors, even, are required to be experienced in mining.

Another objectionable feature which can be improved, is the employment by each side of an army of experts. Practically all extralateral cases resolve themselves, sooner or later, into a battle between opposing experts. This results in great expense as well as a confusing exaggeration of structural details of minor importance. In a great majority of cases justice could be as readily obtained by a board of experts, one to be selected by each side and a third by the judge of the court, the expense to be shared equally by each party. These experts could examine the properties involved and make a report on the geological occurrences. They would agree on most facts, and where there was a difference of opinion litigation work could be ordered to further develop the points of difference. This plan would eliminate much of the expense and time consumed in such trials, and would obviate a plunge into untried hazards which are bound to follow a radical change in the law.

If it is litigation we wish to avoid, then why not also compel all locations in future to conform to legal subdivisions. Requiring lode-claims to be located in con-

formity with public-land surveys, as is now required in the case of placers, and also registering all locations in the land offices, would eliminate ten-fold as many cases as by abolishing the extralateral right; but by each of these remedies the advantage of economic operation of the ore deposit as a geological unit would be sacrificed. The vein on its dip into the earth has nothing in common with the surface, and to parcel it out by surface area and vertical boundaries is a structural misfit, and so would be the forcing of lode-locations into rectangular surface areas conforming to the public-land surveys.

Most of the mining laws of other countries recognize severance from the surface itself of minerals lying underneath the surface. The owner of the surface does not usually own the minerals lying in depth beneath his surface, but a separate property exists in these underlying minerals which the State may grant to another person. As a result there is no serious conflict between the surface owner and the individual who is entitled to work the mineral deposits beneath the surface. The law of ownership of lands acquired on the public domain of the United States, on the contrary, only recognizes such severance to a limited extent. Recent legislation by Congress does permit agricultural entry of lands valuable for coal, oil, gas, phosphates, nitrates, potash, and other non-metallic minerals. 'Known lodes' are also excepted from placers and 'known mines' from townsites. The agricultural patentee is further safe-guarded in this country by a statute of limitations, which provides "that suits to vacate and annul patents thereafter issued shall only be brought within six years after the date of issuance of the patent." Not only does this statute of limitations operate to cut off a mining claimant's opportunity to acquire mineral already known to exist in patented agricultural ground, but rulings of the Supreme Court of the United States and of various State courts have thrown additional protection around agricultural claimants, so that after their *bona fide* entry on land under non-mineral public land laws has been made, it is difficult for a mineral claimant to make a valid adverse entry on the same land.

In other words, when the United States grants non-mineral title to land there is no dual ownership contemplated except in a few limited cases. Hardship is going to result to the miner if the extralateral right is abolished without the simultaneous enactment of legislation designed to offset this difficulty. The result of an outright elimination of the extralateral right will be to feed existing agricultural patents which have veins dipping beneath them with all such extralateral segments of such veins situated vertically beneath, since such segments will fall by gravity into and become merged with the ownership of the overlying surface lands. Some may argue that this is a desirable result. It is doubtful whether the mine operator and prospector will enthuse over such an outcome. To allow minerals to pass into agricultural ownership is not going to facilitate the extraction of minerals from the soil.

The main exception in the public land law of the

United States existing today which takes the place of severance in other countries, is the right of the owner of a valid lode-location embracing the apex of a vein to follow the vein extralaterally underneath adjacent surface. In other words, the extralateral feature of American mining law operates to segregate mineral deposits in the nature of lodes or veins from the surface land overlying the dip of such veins or lodes. The practical result of abolishing the right to follow a vein extralaterally and also of abolishing the discovery-requirement, would be that agricultural claimants could readily file on and enter upon land overlying the dip of the vein. Under the existing land laws there is no way to prevent such action unless the Land Department can be persuaded to withdraw the land from agricultural entry pending its classification, manifestly impossible in every instance, as well as interfering with *bona fide* acquisition of agricultural titles. With the extralateral law in force, the locator can locate a claim embracing the apex of the vein and make a valid discovery on the portion of the vein which is nearest to the surface. Abolish the extralateral right and it becomes difficult and, in many cases, impossible to discover mineral within the vertical boundaries of claims overlying the dip of the vein.

If any change is to be made in existing law, and if conditions are to be improved rather than made worse, instead of abolishing the principle of the extralateral right, it should be carried even further by amendment of the public-land laws providing for the severance from surface lands of all minerals except superficial deposits. Surface lands could be disposed of under existing laws providing for the acquisition of agricultural and other non-mineral titles except that the mineral should be permanently reserved from such surface grants. As the law now stands, and as has already been noted, only minerals known to exist at the date of the agricultural grant are reserved, and even such minerals become the property of the surface proprietor by virtue of the existing statute of limitations, and also the additional protection thrown by the courts about a surface proprietor in possession. By reserving minerals from agricultural lands, and allowing the miner the right of entry for purposes of prospecting under restrictions with the added requirement that the surface proprietor be compensated for damage, the interests of both the miner and the agriculturist would be conserved. In all the important mining countries of the world this segregation has taken place and this is the reason why in such countries the extralateral principle is not essential, whereas, in the United States, without such segregation or severance of minerals from the surface, the extralateral right has a powerful additional reason for existence. With severance of minerals and segregation of agricultural and mineral interests, the element of discovery also, now so vital in the mining law of the United States, would assume secondary importance. If the principle of severance is incorporated in a revised public-land law, a vertical boundary system for the acquisition of mineral lands could be adopted simultaneously without resulting in great hardship to the

miner, for the agricultural surface claimant could no longer claim the underlying minerals. The surface perimeter within which the miner could work should be so adjusted as to give him as much opportunity as possible to mine in depth on the vein. This would in effect be an adoption of the French system of mining law. However, a radical change of this sort would unquestionably result in increased supervision of mining operations by the Federal Government and conversely a material sacrifice of individual control over such operations. It might even result in permanent reservation by the Federal Government of all minerals, metalliferous as well as non-metalliferous, and their disposition under a leasing system. This would be in line with the new public-land policy as evidenced by recent acts of Congress and of the executive branch of the Government which have been upheld by the United States Supreme Court. The Federal Government has provided for such severance in the case of lands containing coal, oil, gas, phosphate, and similar minerals, and it may be that the experience derived from the practical development of such lands will aid in determining this serious problem when applied to the metalliferous minerals. The severance of surface title from the underground minerals would also discourage speculators and blackmailers who now fraudulently seek to acquire title to surface lands under agricultural laws in order to levy tribute upon the *bona fide* mining operator.

The complex problem here presented is surrounded with profound difficulties and no matter in which direction we turn, we are confronted with unknown quantities and untried conditions. It will take a master mind to hew the way and devise a substitute law which will work in harmony with our other land laws and which will not bring chaos in its wake. It is certain that if revision is desirable it should not take place piecemeal and without due consideration of its effect on other land laws.

I feel justified in asserting that the following summarized statements are amply supported by the facts:

1. The extralateral right principle has existed in one form or another in many of the mining laws of the world but in nearly all instances this feature has been eventually abolished because of the litigation and uncertainty which it produced.

2. The extralateral right was adopted as a part of the mining law of the West by the pioneer miners when they made their earliest quartz locations in 1850 and 1851 and it became the almost universal custom and usage of the miners throughout the mining districts to exercise 'dip rights.'

3. The legislatures of practically all of the Western States and Territories had by statute declared the extralateral right to be the mining law in force in their respective jurisdictions when Congress passed the Act of 1866 which adopted and crystallized this miner's law without material alteration.

4. The Act of Congress of 1872, which is still in force, further codified and confirmed this miner-made law, changing it only in minor respects, and leaving the fund-

amental principle of extralateral pursuit substantially as the miners had originally adopted it.

5. The law of discovery is not only handed down to us by the pioneer miners of the West but is also a heritage of centuries of mining experience throughout the world.

6. To abolish the extralateral right will result in forcing the abolition of the principle of discovery as applied to lode mines as well, and these are two of the most vital features of our mining law.

7. With the extralateral right repealed, the only important feature of our law which has the effect of severing the underlying mineral from the surface will have been eliminated, and with the principle of discovery eradicated, the simple and practical test, now thoroughly understood, will no longer be available to the prospector and locator, and unless some substitute is furnished he will find himself at the mercy of the agricultural claimant or the unscrupulous speculator.

8. The alternative suggested of leaving classification of lands to government agents will shift the initiative in determining mineral character from the individual locator, as it exists at present, and will be a long step in the direction of complete Government control of metalliferous mining.

9. The logical solution based on world experience is to sever all mineral except superficial deposits from the surface, and dispose of the minerals and the surface separately.

10. Whether a workable system based on this principle of severance can be devised at this late day which will not result in producing greater confusion and more litigation by reason of new and untried problems and conflict with innumerable rights vested under the former system, is a question which would tax the wisdom of Solomon.

11. Revision, if attempted, must be general and not piecemeal, and should be enacted only as the result of the most careful deliberation by a commission composed of the best talent available.

Acieral, an Aluminum Alloy

An alloy containing 92 to 97% aluminum and offered as a metal of strength and lightness and non-corrosive, suitable for use in the construction of automobiles, aircraft, military equipment, railroad cars, valves, hardware, etc., has recently been put on the market. It is called acieral and is the discovery of M. de Montby. It is being supplied to the French government for the manufacture of helmets. It is silver white, has a specific gravity of 2.82 and a melting point of 1382° F. Its tensile strength in castings is given as 30,000 lb. per square inch, and in rods and sheets as 28,000 to 64,000 lb., and heat-treated as upward of 70,000 lb. per square inch. It is claimed that it may be sand-cast, die-cast with or without pressure, hot and cold forged, annealed, drawn, rolled, stamped, hardened by temper, polished, electroplated, and soldered. It withstands the action of all acids except hydrochloric.

The Pazña Tin-Mining District, Bolivia

By FRANCIS CHURCH LINCOLN

INTRODUCTION. The Pazña tin-mining district is in the department of Oruro, in west-central Bolivia, South America. It lies nearly at the geographical centre of the great Bolivian tin belt, which follows the general trend of the main range of the Andes from Carabuco near the Peruvian boundary to Portugalete not far from the Argentine border. It also lies close to the productive centre of this belt, for the two largest producers—Uncia and Llallagua—are only some 20 miles to the east; Huanuni, another of the big mines, is about 20 miles to the north; while the Aramayo Francke mines, which compete with Huanuni for third place, lie a considerable distance southward.

PROPERTIES. The following table gives the names of the principal mines and mills in the Pazña district, their owners, and the rates at which they were producing in the fall of 1916. The production is stated in short tons of concentrate (locally known as 'barrilla'), containing 60% or more of metallic tin. For comparison, it should be noted that the local unit of weight is the 'quintal,' about one-twentieth of a short ton (46 kilo), so that the figures in the table may be changed from tons to quintals by multiplying by 20.

TABLE I. PRODUCTIVE MINES OF THE PAZÑA DISTRICT

Mine	Mill	Owner	Monthly production in short tons of concentrate
Chualla Grande	Avicaya	Abelli y Compañía	60
Exaltación	Totoral	Sociedad Estañífera de Totoral Consolidada	45
Chuncho	Antequera	Nueva Compañía de Estano de Antequera	10
Various small placers near Antequera			35
Total			150 tons

All of these properties are on Chualla Grande mountain. The Chualla Grande, Exaltación, and Chuncho mines are situated on the western, eastern, and northern slopes of the mountain, respectively. Tin has also been discovered in the southern part of the mountain, and prospecting operations are in progress there at present though as yet no production has been made. Search for ore is also being made on the flat plain, at the foot of the mountain, where numerous test-pits are being sunk on the Avicaya placer to determine its tin content.

GEOGRAPHY. Pazña is a small town with a station on the Antofagasta-Bolivia railway. It is 530 miles from Pazña southerly to the port of Antofagasta, in Chile, 45 miles northwesterly to the important Bolivian city of Oruro, and 147 more to La Paz, the principal city of Bolivia, which has railway connection to the Chilean

port of Arica, and railway and steamer connection to the Peruvian port of Mollendo.

Pazña lies upon the Bolivian plateau at an elevation of 12,140 ft., just to the east of Lake Poopó, which mysteriously swallows up the waters of Lake Titicaca flowing into it through the Desaguadero river. Avicaya, where the principal mill of the district is situated, is five miles by good road north-easterly from Pazña at an altitude of 12,510 ft. The Chualla Grande mine, which

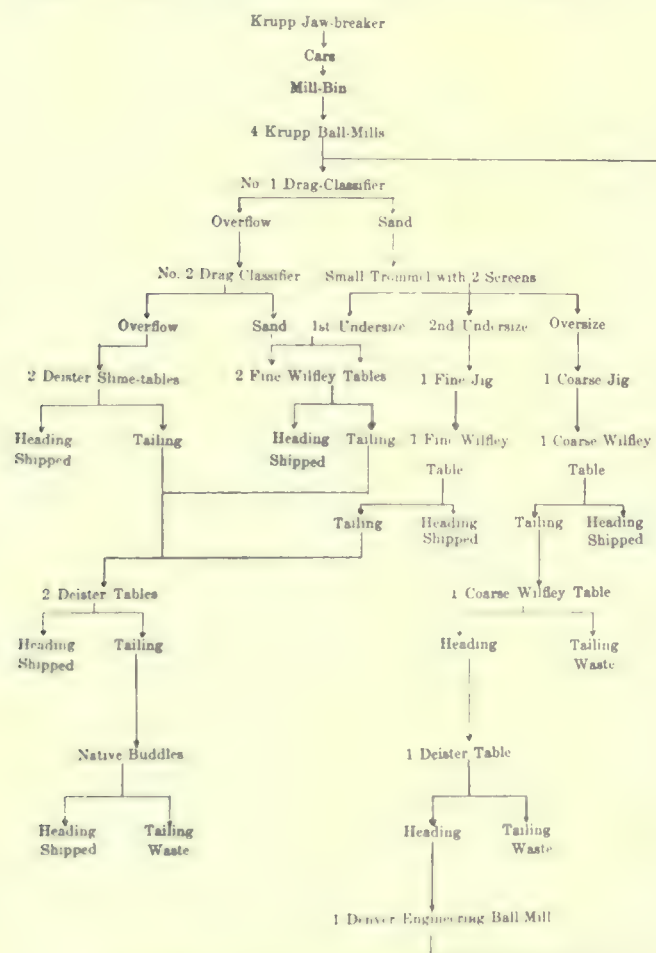

MAP OF BOLIVIA

supplies this mill, is behind the mill on the western side of the mountain near its top. It is 14,630 ft. high, the mountain being 170 ft. higher. The Totoral mill is two miles by road from Avicaya, but its Exaltación mine adjoins the Chualla Grande at the summit continuing down the eastern slope as Chualla does down the western. The Antequera mill is six miles from Avicaya by road, and the Chuncho mine, which supplies it with ore, lies on the northern slope of Chualla Grande mountain.

GEOLOGY. The topography of the region is glacial. Small cirques occupy the top of Chualla Grande mountain, and the mine is in one of these.

The country-rock of the Pazña district is quartzite,

which has been intruded by dikes of quartz-porphry. The quartzite beds dip westerly at from 30° to 45° . At the Chualla Grande mine there is one quartz-porphry dike cutting a lode in depth, and another intrusive in a lode in much the same manner as that at the Concordia mine in the Quimsa Cruz district described in a previous article.* The geology of the Exaltación mine in the Pazña district has been outlined by Rumboldt† who

FLOW-SHEET OF AVICAYA TIN-CONCENTRATING MILL.

makes brief mention of the other mines of the district; and a few notes on the district, mainly mineralogical, have been given by Romaña.‡

At the Chualla Grande mine there are seven important veins, which, in order from east to west, are the Almacen, Dique, Carmen, San Francisco, San Luis, Parada, and Hospital. These veins roughly follow the bedding of the quartzite, but, after the manner of many Bolivian tin lodes, they show a tendency to join and branch both in dip and strike and thus to form a linked-vein system. They vary in width from 3 to 30 ft. and have been explored to a depth of 585 ft. Farther to the westward and at a lower elevation, the Minchin adit has cut numerous narrow tin-bearing lodes.

The ore-shoots are generally widest near their out-

crops, decreasing in width with distance from the surface both laterally and in depth, although the mineralized beds may retain their surficial widths. The oxidized ore is also, as a rule, the richest, the sulphide ore being not only narrower but also poorer in tin. The primary ore consists mainly of cassiterite, pyrite, and quartz, with minor amounts of tourmaline and occasional chalcopyrite. In the oxidized zone the pyrite has been altered to iron oxides. Discussing a thin section of the ore as seen under a microscope, Romaña says that "together with the quartz a little orthoclase has also been deposited, and it appears that there are some crystals of corundum," but these minerals have not been recognized with the naked eye. Higher than the tin lodes, on either side of the highest peak of Chualla Grande mountain, stringers of wolframite an inch wide have been found, but it has not yet been observed in the tin-bearing veins.

MINING. The Chualla Grande mine is owned by Abelli & Co., Mr. Abelli having recently taken up his residence in the United States. M. F. Grondijs is consulting engineer, Ernst Schrenberg is manager, Ladislav Jackowski mine-superintendent, and Pablo Hahn mill-superintendent.

Miners receive from 2.80 to 3.20 *bolivianos* per day, which at present rates of exchange is \$0.93 to \$1.07. Helpers get 2.20 to 2.40 *bolivianos*, or \$0.73 to \$0.80. Both rock and ore are extremely hard, so the cost of mining is high for Bolivia.

The Almacen, Carmen, San Francisco, and San Luis veins are now being worked, and the Minchin adit is being driven toward the Ballivián shaft. This adit was started at an elevation 920 ft. lower than that of the little plaza just below the main workings. The shaft is farther west, and as the veins dip to westward with the slope of the mountain, its collar is but 770 ft. above the level of the adit. The shaft has a depth of 585 ft. and thus lacks 185 ft. of reaching the adit-level; while the adit, which already is about 3000 ft. long, has yet over 400 ft. to go to reach the projected shaft.

Machine-drilling proved impracticable in the adit, because the heavy blows struck by the big drills against the very hard rock necessitated an excessive expenditure for repairs, and the adit is now being driven by hand at a rate of only 13 ft. per month. The cost of driving has at times reached \$17.20 per foot. Four stopers and two jack-hammers are at present employed in the mine, but the use of column-drills has been discontinued.

MILLING. The Avicaya mill is now being remodeled and is only treating some 25 tons of tin ore per day, but when the changes in progress have been completed it is expected that it will have a daily capacity of 50 tons. The ore is said to average about 5% metallic tin and the tailing to run under 1%.

The ore is brought to the mill by aerial tramway. It passes first through a Krupp jaw-breaker and is then trammed by hand to a bin. From this bin, it at present goes to four Krupp ball-mills, but two 5-stamp batteries are being installed to replace these. The remainder of the concentrating process is shown in the flow-sheet.

Concentrates

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

BLOWPIPING, in the determination of minerals, is more readily done with the flame of an ordinary candle than with either gas, alcohol, or oil, in the hands of a skilful operator. Most expert blowpipers prefer the candle-flame, using a hard adamantine stearic-wax candle. It is possible to manipulate the flame so skilfully as to oxidize a borax bead, containing a copper-test, at one end, and to reduce it at the other, so that one part of the bead will be blue and the other will show the red metallic copper.

CHROMIUM may be detected, even when present in minute quantities, by fusing the suspected substance on charcoal with sodium carbonate. If much chromium be present the resultant slag will have a greenish color. Pulverize the slag and dissolve it in water. Acidify the solution with acetic acid, and add a few drops of a solution of silver nitrate. A reddish brown precipitate of silver chromate will be thrown down. The reaction is so delicate that mere traces of chromium will thus be shown.

QUOTATIONS on certain ores and metallic products, such as antimony, chrome, manganese, and tungsten, are based on the unit. A unit is one per cent; therefore, when the short ton (2000 lb.) is used, the unit is 20 lb., but when sales are effected on the basis of the long ton (2240 lb.) the unit is 22.4 lb. In the case of manganese, settlements are made on the long ton, where the unit is 22.4 lb. of the metal, but tungsten is sold on the short-ton basis, and the quotations refer to the unit of 20 lb. of the contained tri-oxide, WO_3 .

THE EXTRA-SOLUTION employed in the Russell process of lixiviating silver ores by a solution of sodium-hypo-sulphite was made by mixing in solution two parts of the hypo-salt with one of copper sulphate, the result being a double salt known as copper-hyposulphite. It is claimed to have a solvent power nine times as great as the ordinary hypo solution, and was used successfully in treating some refractory silver ores. The method was described in great detail by Ellsworth Daggett in the Transactions of the American Institute of Mining Engineers.

IODINE is frequently associated with phosphates in sufficient quantity to be worth extracting. The method of Thiercelin, a French chemist, for accomplishing this consists in treating the phosphate with equal quantities of sulphuric acid and water in a tank provided with means for agitation. The reaction proceeds under the influence of the heat generated during the dilution of the sulphuric acid, and the iodine is liberated in the form of vapor, which is condensed in a suitable chamber. A modification of this method consists in leaching the alkaline iodide and electrolyzing the filtrate, using a

carbon anode and an iron cathode. The iodine is liberated at the anode, is collected, washed with cold water, and dried in a current of heated air.

FROST-RESISTANCE of building-stones may be tested by soaking the stone in a solution of sodium sulphate, and allowing it to dry. The expansion of the crystals in the pores of the rock exert a pressure greater than frozen water, so that the test is particularly severe. A stone that will not scale off badly under this treatment may be considered to be highly frost-resistant. A good sand-stone tested in this manner should show a loss in weight not exceeding 50 to 60 parts in 10,000; a granite should not exceed 8 to 15 parts, and a marble not more than 15 to 20.

TRAPICHE is a Chilean application of the word by which a cane-mill is commonly designated throughout the sugar-growing countries of Spanish America. In this special use, which is also noted in Mexico, it signifies a type of Chilean mill which consists of a beam, at one end of which a revolving wheel-stone is fixed so as to turn as upon an axle, a pivot being provided on the beam not far from the stone, while the longer end extends beyond the circular grinding-pavement so as to gain the advantage of considerable leverage, thus enabling a mule to revolve the stone.

FIXATION of nitrogen with manganese has been investigated by Haber, the inventor of the now famous Haber process of combining nitrogen directly with nascent hydrogen. Finely divided metallic manganese is heated to redness in a stream of nitrogen. The result is the formation of pentamangandinitride, Mn_5N_2 . Haber, however, suspects that the nitro-manganous substance formed may possibly consist of Mn_3N_2 , associated with oxides of manganese, which seems most probable. It possesses a dull metallic lustre, and is feebly magnetic. On being treated with water and alkalies it yields ammonia.

CHLORIDIZING of copper, by treating cinder from cupriferous pyrite with common salt, yields cupric chloride, CuCl_2 , which is soluble in water. For a successful chloridizing roast the ore and salt must be finely divided and intimately mixed, there must be free access of air, and the charge must be vigorously rabbled. The amount of sulphur present should equal that of the copper. The temperature at which the operation is conducted should not exceed 600°C ., and 500°C . is sufficient to promote the reactions. Hot water extracts about 75 to 85% of the copper present, yielding a metal of great purity. The remaining copper is extracted by a first treatment with 'tower-liquor,' an impure acid-liquor obtained by passing the roast-gases through a quartz-filled tower through which water trickles. In this the larger part of the copper, not previously taken out by the water, is dissolved. A final treatment with 8° Baumé sulphuric acid for 2 to 3 days extracts the greater part of the residual copper.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

OATMAN, ARIZONA

THE NEW TOM REED MILL COMPLETED.—A RADICAL CHANGE IN METALLURGICAL METHODS.—IMPORTANT DEVELOPMENT OF OTHER PROPERTY OWNED BY THE BIG JIM COMPANY.

May 25 was the date officially fixed by superintendent Edward M. Rabb as the time when the 20-stamp mill of the Tom Reed company will be shut down permanently and the new 300-ton Allis-Chalmers ball-granulators will begin the fine crushing of the ore for cyanidation. It will be ten years, almost to a day, since the first 10 stamps of the Tom Reed company were set in motion. During that time the company has

two 300-ton Merrill precipitating-presses. The precipitated solution from the presses flows by gravity to a barren-solution storage-tank, the solution from this tank passing by gravity to the decantation-tanks, thus entering the mill-circuit again. The precipitating-press room together with the melting-plant and roasting-furnace, will be situated at the top of the mill.

The underflow of pulp from the primary thickener will pass through four 12 by 40-ft. redwood tanks fitted with Dorr agitating-machinery. From the agitators the pulp will be divided into two streams, each stream passing through a battery of four steel Dorr thickeners to counter-current decantation-tanks.

A Leschen aerial-tramway is being constructed, having a

THE NEW TOM REED MILL, OATMAN, ARIZONA

milled a little over 300,000 tons of ore from which \$6,350,000 in bullion was extracted, and \$2,750,000 in dividends paid.

The new mill will have double the capacity of the old one. After the initial crushing, the ore is conveyed to a 300-ton ore-bin from which it is fed into the 5 by 6-ft. Allis-Chalmers ball-granulator by the Reeves and Stephenson-Adams machine. The product from the granulator goes to a Dorr duplex-classifier.

The undersize from the classifier goes to a primary Dorr thickener and the oversize will feed into two 5 by 6-ft. Allis-Chalmers fine ball-granulators. Two Dorr duplex-classifiers will operate in closed circuit with these ball-mills.

The overflow from the primary thickener will flow to a gold sump-tank of steel. This solution will be clarified by a Butters filter, connected to a Gould vacuum-pump and discharging into a redwood tank.

To the clarified solution from this tank will be added the emulsified zinc-dust from a Merrill zinc-feeder and then elevated 35 ft. by two Rumsey triplex-pumps and forced through

capacity for delivering 300 tons of ore daily from the Aztec shaft to the mill. This tramway will be 4000 ft. long. It is expected to be in operation about June 15.

It is the plan of the management to take ore for the new mill from the Aztec shaft where the vein has been opened up by driving on both the 400 and the 535-ft. levels.

This will afford an opportunity to open up the 1400-ft. level at the Ben Harrison workings of the company from which practically all the ore milled during the past ten years has been taken. The main shaft will be extended down to the 1400-ft. level, which is now reached only by a winze.

The annual report of the company now being sent to the stockholders shows ore reserves of 54,000 tons in the old workings, not counting any of the ore recently developed in the Aztec claims. About 46,000 tons of ore was milled during the past year averaging \$11.03 in gold, which cost \$6.48 per ton to mine and mill. Over \$200,000 has been expended during the year in development and in constructing the new mill. A net profit of \$131,000 was returned from the year's operations.

MAGDALENA, NEW MEXICO

LEAD-ZINC MINES ACTIVE.—THE EMPIRE ZINC COMPANY EXPANDING.—VALUABLE DISCOVERY OF ASBESTOS.

At Kelly, the mining district about three miles from Magdalena, a period of great prosperity has set in. More men are being employed now than at any time in the past. Many new improvements have been made in the district during the past few months, and large sums have been expended by the companies in putting the works in good condition. The Empire Zinc Co. is re-opening and re-timbering a new shaft, which was sunk last season from the tenth level to a depth of 108 ft. The work was stopped before on account of water, which made it necessary to abandon the project for a time. The ground caves badly and cannot be held by ordinary means. The present effort, however, is meeting with success. It is intended to sink to a depth of 300 ft. to get under a large body of ore. The ore is said to run high in zinc and copper. The company is considering the construction of an aerial tramway from its Lynchburg mine to the mill. The smelter, which was destroyed by fire last year, has been re-built and greatly improved. A large number of men are employed at that plant.

A large number of natives of Mexico are employed in the mines of the Magdalena district, and, contrary to the fears of many, and the frequent rumors of the seditious intentions of the aliens, the miners have been found to be, in the main, a peaceable lot and unaffected by the outbreak of hostilities between the United States and Germany.

A discovery which is interesting a number of people in this district is asbestos in the vicinity of Reserve, a small settlement in the western part of the county. Fine specimens were picked up by J. C. Smith, of Magdalena, who chanced to observe it while passing. The outlook is sufficiently promising to warrant the sinking of a shaft, which is now being done. H. Mangold, of Oregon, who is experienced in asbestos, has reported favorably upon the find. Villages are springing up between Magdalena and Kelly, making it probable that in a few years there will be one large town to take the place of the several scattered camps, if the increasing prosperity of the mining industry here continues.

LEADVILLE, COLORADO

DEVELOPMENT OF THE MIKADO MINE BY THE IRON SILVER COMPANY.—NEW MACHINERY EQUIPMENT.—PROSPECT OF LARGE PRODUCTION.

With the recent completion of its plant at the Mikado shaft, on Iron hill overlooking Stray Horse gulch, the Iron Silver Mining Co. has perfected the most substantial and modernly equipped property now operating in the Leadville district. The construction of this plant has required more than a year of continuous labor under the direction of George O. Argall, manager, and Ralph Poole, superintendent. The expenditure reaches nearly a half million dollars. The project was undertaken early last year when the Iron Silver Co. secured control of the Mikado, R. A. M., Pyrenese, and other surrounding properties located in the centre of the Graham Park basin; and completed plans for draining this area through the Mikado shaft. Pumping equipment for the enterprise was ordered in April a year ago, and at that time the work of preparing the shaft for unwatering and erecting a surface-plant was started. The task of replacing the old plant at the Mikado with the present substantial and up-to-date equipment, and of draining and re-timbering the shaft has been a big one, and its successful accomplishment is an evidence to the knowledge and able management of the men who have had charge of the work. The re-timbering of the shaft from the collar to the water-level, which, at that time, stood at a depth of 912 ft., was first undertaken employing the old machinery and plant. This work was rushed in order that the shaft might be in condition to re-

ceive the heavy pumping-equipment which had been ordered for 90-day delivery. This haste, however, was unnecessary, for after repeated delays in shipment the machinery did not arrive until April of the present year. While re-timbering was under way, the construction of a new surface-plant was in progress. A 40 by 80-ft. structure was built and divided into two 40 by 40-ft. rooms for housing the machine and blacksmith-shops, and a 35-ft. head-frame of Oregon fir was erected over the shaft. At this stage, the shaft work was completed to the water-level, and the old engine-room, head-frame, and old hoist were removed. This done, concrete foundations for the new hoisting-machinery were laid and construction was started on the new engine-room, office, store-room, and the housing over the shaft.

These buildings have been equipped with the finest plant of electrically driven machinery in the district. A Wellman-Seaver-Morgan double-drum hoist—the largest power-hoist in the district—driven by a 300-hp. motor has been installed in the engine-room, together with an Ingersoll-Rand air-compressor of 1080 cu. ft. capacity driven by a 200-hp. motor. The hoist is equipped with a Welsh safety-device and the compressor with an automatic-unloader. The machine-shop is completely equipped with power-driven machinery, including a lathe, drill-press, pipe-cutter, bolt-cutter, hack-saw, emery-wheels, grind-stone, and other appliances necessary to the upkeep of the plant. In the blacksmith-shop, a large air-hammer, shearing-machines, drill-sharpener, and chain-blocks are installed. The office is modern, and the store-room has every facility for taking care of supplies. The housing over the shaft is a two-story structure to accommodate two hoisting decks. It is steam-heated and contains a commodious room where the men change their clothing and eat their lunch.

A large transformer-house of structural-steel frame and sheet-iron covering has also been erected and equipped with transformers. A repair-pit of concrete has been built-in to facilitate overhauling the transformers. An aluminum-cell lightning-arrester is also installed in the transformer-house, and the power-load consumed is registered by a polyphase watt-hour metre.

At the present time, the boiler that supplies steam-heat for the plant, is installed in an old building. This, however, is to be removed, and the boiler will be placed in a new ore-house that is to be erected.

Surface-lighting is provided by three 500-watt searchlights which have been installed at advantageous points by the Colorado Power Company.

Underground progress has been made with the installation of pumping-equipment, draining, and re-timbering the shaft. Since the heavy pumping-machinery for the project was ordered last year, draining has been through the Wolfstone and Greenback properties adjoining the Mikado. The latter shaft is 1350 ft. deep, and the pumping there has materially decreased the flow in the Mikado, making it unnecessary to install the complete draining-plant. At the 900-ft. level, a new station has been cut, and one of the two station-pumps ordered has been installed. These machines are six-stage horizontal centrifugal-pumps driven by 500-hp. motors and are capable of lifting 1000 gal. per minute under a 1200-ft. head. They were manufactured by the Worthington company. Drainage of the shaft is being performed by a small air-sinker that handles about 40,000 gal. every 24 hours. It discharges into a reservoir on the 900-ft. level. This reservoir has a capacity of 25,000 gal. and is emptied twice daily by the centrifugal station-pump. Two sinking-pumps of the four-stage vertical centrifugal type with a capacity of 1000 gal. under a lift of 350 ft. are stored at the property ready to be installed when needed.

Re-timbering in the shaft below the 900-ft. level is still in progress but is rapidly being completed to the bottom at a depth of 1200 ft. This task has been a most difficult one from the beginning. The Mikado is the largest shaft in the district being 5 by 15 ft. in the clear and divided into three compartments. From the collar down to a depth of 100 ft. it was neces-

sary to crib the shaft. Below that point square-sets of Douglas fir have been used. From the 900-ft. level to the bottom, the shaft originally had only two compartments. From that point to a depth of 1070 ft., where the work is now under way, it has been necessary to cut a new compartment and remove one foot of rock on each of the other three sides before timbering, so that progress has been comparatively slow. Protection to the shaft has been provided by the erection of two sheet-iron doors in the hoisting-compartment just above the point of operations.

One compartment which has been devoted to the accommodation of the water-column and power-cables, has been divided into two sections. In one of these, a small service-cage will be installed and handled on a steam-winch to take care of the hoisting and lowering of men and supplies. It will take the place of a ladder-way and give more rapid service and at the same time leave the two main compartments free for hoisting ore and waste.

On the 1000-ft. level, the work of re-opening the old drift is in progress and will be pushed ahead to the large orebodies known to exist in that part of the property.

The shaft is equipped with an electric-bell signal-system, and mine-telephones are being installed at the two levels now open.

The Iron Silver Mining Co. is one of the oldest operators in the Leadville district, having been engaged in the development of the Moyers, Iron Mine, and Tucson properties for a number of years. Operations are still in progress at these mines, but the centre of activity has been changed from the Moyers, in California gulch, to the Mikado which will be the heavy producer of the group in the future. The company's offices have been moved from Oro, near the Moyers, to the Bank Annex building, in Leadville.

MANHATTAN, NEVADA

NEW DEVELOPMENTS OF IMPORTANCE.—HIGH-GRADE ORE IN SEVERAL MINES OF THE DISTRICT.—SHAFT SINKING PROGRESSING.—COMPANIES BEING FINANCED SUBSTANTIALLY.

The important event of the week in mining development in the Manhattan district has been the strike of high-grade ore in the Train-Chase lease on Mustang hill. At an approximate depth of 200 ft., in the bottom of two winzes sunk from the main workings, stringers of rich ore, which were being followed, have opened up from one to two feet into lenses that carry from \$100 to \$200 per ton in free gold, with sulphides averaging as much more. The lessees are bringing to the surface about \$1000 in each shift's work. While the Train-Chase lease has been a consistent producer from the grass-roots to the present depth of 200 ft., having produced over \$35,000, present indications point to a much heavier production. The fact that the present developments show heavy sulphide ore in the winze bottoms, is important, and is thought to indicate that the primary ore-horizon has been reached. The lessees expect that at any time the winze-sinking operations may break into a large and rich orebody, and a mine similar to the White Caps, developed.

In addition to the high-grade ore being produced from the two winzes, a raise is being extended on a third ore-chimney about 40 ft. east of the winze ore-pipes. This raise has been cut to a height of 35 ft. above the level, and the entire face is in ore which will average \$100 per ton. The last 15 ft. in the raise has produced ore of similar grade.

The Doris mine, although north of the main producers in the district, has an attractive showing, with a well-defined porphyry dike. The property is being operated on company account, and during the past few days the value of the ore has shown a marked increase.

The Union No. 9 claim of the Dexter company is showing well through the operations of lessees. The Juhl-Fogle lease is sinking on the same grade of ore as that of its first shipment, running over \$80 per ton in the mill. The lessees' shaft

is down over 100 ft., and although the seeping of surface-water into the shaft necessitated considerable bailing and delayed mining operations to some extent, the flow of water has ceased and shaft-sinking has been resumed. The lease is operating on a new vein—a cross-fissure, almost vertical. Two more lease-blocks have recently been granted by the company and similar cross-fissures are being developed.

The company working-shaft of the Extension is down 100 ft. and driving on a cross-vein is progressing. This vein is at right-angles to the limestone-belt that carries the orebodies and is in the foot-wall shale.

The shaft of the Red Top is down 85 ft., and is in broken limestone, having passed through the shale. The screenings from this limestone carry gold, indicating the proximity of the orebodies to reach which the work is being done. As the shaft is being sunk by hand-work, the company not having yet installed a compressor for operating machine-drills, the footage made each day is small.

Although some delay has been experienced in driving east from the 600-ft. level of the Amalgamated, due to a heavy flow of water, still 16 ft. has been added to the length of the drift within the week. The total length for the east drift is now 184 ft. This is about half way from the company shaft to the Earl orebodies, for which the east drift is being extended. The face of the drift is in low-grade ore which is increasing in value as the face of the drift advances. The fissure vein is showing good ore. A raise on the west orebody has been started, 40 ft. having been made on ore running \$25 to \$40 per ton. The company mill has been running during the week.

The work in the Consolidated during the week has been devoted to cross-cutting from the shaft, 40 ft. having been made through a black lime-shale, which forms the hanging wall of the vein in the upper levels of the mine. The lateral work is proceeding and the only delay possible will be caused from a heavy flow of water from the vein itself. The large Cameron sinking-pump is prepared for such an emergency. In addition to the sinker there is a Deming 4 by 6-in. triplex electrically-driven station-pump ready to install on the level should the flow of water remain constant. The past few feet of the cross-cut has shown numerous calcite stringers which may be taken as a sign that the orebody is near. The conditions in the face of the cross-cut are identical with the hanging wall of the vein as they appeared in the Consolidated upper levels, adjacent to the ore.

The working-shaft of the Morning Glory has reached a depth of 80 ft. Steady work with two shifts has been the rule. The shaft is on the lime and shale contact, west of the White Caps west orebody. The gouge upon which the shaft is being sunk, carries gold. As depth is gained the value of the ore has shown a gradual increase. With a few more feet of depth, upon reaching the point where the orebodies in the lime-belt are expected to be found, the contact should show ore of milling grade.

The company has sent out notices calling for a special stockholders meeting, to be held on May 25, at its Tonopah office. The purpose of the meeting is to increase the capital stock to a million and a half from a million shares as at present capitalized.

* The subscription list for the selling of sufficient shares from the treasury of the White Caps Extension Mining Co. to provide funds for operations, has been filled, as the stock was over-subscribed within three days after it was offered for sale. Preliminary surface work has been started by the company. The management has considered the advisability of sinking shafts, although the plans are tentative. The points where these shafts will be sunk has not been decided.

The operations at the White Caps show steady work both in mine and mill. The shaft has reached a point 45 ft. below the fourth level, with the shaft-timbers all in place. So far, little water has been encountered in the shaft. On the third

level 30 ft. was made during the week, with the face of the drift in oxidized and mineral-stained material, indicating that the contact is being approached. In the west drift, the early part of the week was devoted to allowing seepage water to drain out of the country opened by the drift. In the face of the drift, the ground apparently is out of the faulted zone. The limestone drag carries \$12 in gold. In the mill the roaster-column, shell, and doors are in place. The machinery in the sand-tank building is all in place with tanks, piping, and pumps installed and ready for operation. The mine ore-bin, of 200-ton capacity, is in process of erection and should be finished before the week's end. The excavation and masonry for the installation of the coarse crusher has been finished, and the crusher can be installed at any time; the large belt-conveyor structure is also nearing completion. The new wagon-road, to connect with the Tonopah-Manhattan county-road at Pipe springs, has had 20 men employed steadily during the week.

COBALT, ONTARIO

THE LABOR TROUBLES BECOMING MORE THREATENING.—THE MINE-WORKERS MAKE A FORMAL DEMAND.—A GOVERNMENT COMMISSION EXPECTED TO HANDLE AN ACUTE SITUATION.

Affairs in mining have been comparatively quiet of late, ore and bullion shipments for the second week of May being considerably below average. However, one pleasing feature was the report for April of the Kerr Lake Mining Co. in which it was shown that over 250,000 oz. of silver bullion was recovered, a record in the history of this mine. This company only recently subscribed \$300,000 to the United States Government Liberty Loan.

Nipissing continues to be the leader and during April mined ore of an estimated value of \$259,082, in addition to which \$517,719 in bullion was shipped from the Nipissing customs-plant. The manager reports nothing unusual in connection with development except that operations were satisfactory. Perhaps the most talked of topic on the street is the labor situation, and although wild rumors are heard from time to time, it is generally believed by those who are in close touch with both the mine-workers and the managers that a settlement will ultimately be brought about. Tuesday morning, officials of the Miners' Union mailed a letter to each of the various mine managers of the different camps, including Cobalt, Porcupine, Kirkland Lake, and Gowganda. The letter contained a copy of the wage-scale that has been adopted by the Union, together with a request that a conference between mine-workers and managers be held, and also requesting that a reply be forthcoming by May 31. Several of the managers have openly stated that they will refuse to acknowledge the receipt of the communication, in view of which it is probable the situation will early in June grow more tense. It is considered probable, however, that either before or about that time, a commission will have been sent to Cobalt and Porcupine for the purpose of looking into the situation, and that the commission, acting independently of either mine managers or mine-workers, will adjust all differences.

PORCUPINE AND KIRKLAND LAKE

LABORS DEMANDS THREATEN TO CUT HEAVILY INTO THE PROFITS OF IMPORTANT MINES.—KIRKLAND LAKE MAKES A GRATIFYING DISCOVERY.

In Porcupine, there is nothing taking place that would indicate a serious curtailment of operations except at the Dome Mines. It is generally regretted that even a moderate restriction of operations at the Dome should occur, but on the other hand, such a development will have the effect of releasing labor, thereby adding to the supply at other properties. The McIntyre-Porcupine is, perhaps, in the most enviable

position of all the Porcupine mines, in that mill-heads, at around \$11 to the ton, are sufficiently high to allow for a compliance with what the mine-workers have demanded and also to pay the increased cost of supplies and still to show a large margin of profit. At the Dome Mines where mill-heads maintain at a little less than \$5 per ton, it is a difficult problem to hold costs down to a point where anything like an attractive profit could be shown. On the other hand, the Hollinger with \$8 ore could meet the increased burden and still show handsome returns. The Schumacher mine with \$6 ore is in a position somewhat similar to the Dome, while the Porcupine Crown and Porcupine V. N. T., both of which are treating upward of 100 tons of ore daily, with mill-heads at \$10 or more per ton, could also bear the burden of increased wages to their workers.

The work on vein No. 58, at the Hollinger, continues to attract attention, a large tonnage of high-grade ore having been developed at the 425-ft. level. Developments in other parts of the mine are adding daily to the large ore reserves. Although diamond-drilling from the 1000-ft. level of the McIntyre has been going on for some time, there has been no official announcement as to whether this vein extends into McIntyre property or not.

In January about 1300 men were employed at the Hollinger, the number is now scarcely over 900, which is an index of the heavy falling off in available labor in Ontario.

In the Kirkland Lake district there is much activity, the most important development being at the 600-ft. level of the Kirkland Lake Gold mine. A short time ago the vein at this depth was reported to have been proved to be 27 ft. wide. According to advice received here, a small horse of country-rock was cross-cut and the vein is now said to be 46 ft. wide. This property is under option to the Beaver Consolidated Co. of Cobalt, the total purchase price being approximately \$308,000. The first payment of \$75,000 was made early in the year, and the second payment of a like amount is due May 22. This payment, it is understood, will be made promptly. The new mill at the Teck-Hughes is treating about 50 tons of ore per day, and mill-heads are around \$10 to the ton. The Tough-Oakes is recovering in the neighborhood of \$70,000 in bullion per month, and the current year will probably be the most productive in the history of this mine. The installation of a new mill at the Lake Shore is proceeding.

CRIPPLE CREEK, COLORADO

AN IMPORTANT SURFACE DISCOVERY ON BEACON HILL.—LESSEES DEVELOPING AND BREAKING PROFITABLE ORE.

A promising surface discovery has been made by Thomas Keating on the north end of the property of the Albert-Beacon Mines Co., on the south-east slope of Beacon hill. Ore valued at \$40 per ton was exposed and mined at a depth of 15 ft. and the first shipment of 30 tons was loaded out by team last week.

Operations were resumed at the Rex mill on the southern slope of Ironclad hill by Thomas Kavanaugh, a well-known operator, who is working the property under lease.

The low-grade ore of a value between \$2 and \$3 per ton is being mined from the big open-cut on the Magna Charta claim, and Kavanaugh is treating this ore at a profit. The mill and Magna Charta claims are owned by the Rex Gold Mining & Milling Company.

Hahnwald Bros., lessees and operators, are sinking the Jackson shaft of the Gold Sovereign Mining & Tunnel Co. Stopping is at a standstill until the shaft has reached a depth of 1500 feet.

The Dante mine resumed operations on May 19, in charge of Mr. Johnson, the superintendent, representing Denver lessee-operators. Four sets of sub-lessees are breaking ore and shipments will be shortly resumed. The Dante Bull Hill mine has a production record of \$1,120,951 gross to date.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The Golden Gate 10-stamp mill, on Chichagoff island, is reported to be in operation again. It was shut-down for several months during mid-winter owing to a shortage of water, which is taken from a lake, but the pipe-line became clogged with a mud-slide. The debris having been removed, the mill now has an abundant and continuous water-supply.

ARIZONA

(Special Correspondence.)—Arizona copper production this month is going at the rate of better than 75,000,000 lb. All the smelters have been loaded down with ore during the month, the mines being more than equal to the higher rate of output. In consequence the mines have diverted considerable labor from production to development and are crowding it. The Calumet & Arizona's reputation for speed has been given another advance by the attainment of 68 ft. of sinking in its four-compartment shaft on the Gadsden in the Jerome district, in one week. The equipment of this property is the largest ever placed on a prospect in Arizona.

Bisbee, May 18.

PIMA COUNTY

(Special Correspondence.)—The New Cornelia Copper Co. will be outputting copper, ready for delivery to the consumer from its plant at Ajo, early in June, a month ahead of the time fixed when plant-construction was commenced.

Ajo, May 18.

YAVAPAI COUNTY

(Special Correspondence.)—The United Verde Extension is to have an ore-haulage adit in service by June 15, 1918. It will be 13,500 ft. long and will cost approximately \$500,000. It will give the Jerome district its second great haulage tunnel, that of United Verde being in successful operation from the 1000-ft. level, receiving ore from both above and below that depth. The Extension adit will connect with the 1300-ft. level of that mine.

Jerome, May 18.

On Thursday, May 24, miners working in the large copper producers of the Jerome district went on strike, demanding higher pay. It is said the strike was instigated and is being directed by the International Union of Mine, Mill, and Smelter Workers. On Saturday, May 26, the sheriff and 25 deputies were in charge at the United Verde mine, and up to that time there had been no disorder. The union men, according to press dispatches, claim that every mine in the district, except the United Verde and United Verde Extension is closed, and that 80% of the men employed in the two mines mentioned are also out.

A press dispatch from Phoenix, dated May 28, states that a mob of strikers is dragging workmen who refused to join the strikers, through the streets, and some of the men have been seriously injured. It is said the local authorities are unable to handle the unruly element. There are several hundred strikers parading the streets and threatening the destruction of property. Governor Campbell and Col. J. J. Hornbruck, who have been directed by the War Department to preserve order in the district, have gone to Jerome. John McBride, former president of the American Federation of Labor, who has been appointed to act as conciliator by Secretary of Labor Wilson is now at Jerome. The city council of Jerome has forbidden women and children to go upon the streets in the business dis-

trict. There is much interest in the progress of this strike in a prohibition State, being the first important strike that has taken place in the mines where it is supposed that it will be impossible for the strikers to obtain liquor.

ARKANSAS

NEWTON COUNTY

The old Confederate mine, on Haw branch of Cane creek, is again in operation after many years of idleness, and a concentrating-mill with a daily capacity of 350 tons is being built. The old workings are being cleaned out and extended and preparations are being made for a large and steady production. It was here during the Civil War that the Confederates obtained a large amount of lead which was cast into bullets. There is also current a story to the effect that a great deal of saltpetre was obtained from caves along Cane creek, a small stream 16 miles long. The nitre was refined on the spot by boiling the crude mineral in large kettles and then evaporating the liquor after filtering.

CALIFORNIA

The petroleum industry of California is expanding constantly. Reports filed with the State Mining Bureau for the week ended May 19, show 29 new wells started, making a total of 433 since the first of the year, 17 wells ready for test of water shut-off, 9 deepening or re-drilling, and 3 wells abandoned.

CALAVERAS COUNTY

(Special Correspondence.)—The Hexter drift mine, on Stockton ridge, a mile and a half from Mokelumne Hill, has 1000 ft. of the channel opened, and the company, the Stockton Ridge Consolidated Mining Co., is only awaiting the arrival of its engineers to begin work. H. S. Chapman is superintendent.

The Buffalo gravel mine, in Chile gulch, a mile from here, is about to resume operations. They have been shut-down owing to delay in getting machinery from San Francisco. The mine has a record as a profitable producer in the past.

In Happy Valley, the Emerson mine is being prospected by W. H. Morrison and associates of Stockton. They are experimenting with a machine designed to save the fine gold in the gravel. The mine was at one time worked by hydraulic method and was profitable, but with the many others was shut-down when hydraulic mining was inhibited, nearly 40 years ago.

Mokelumne Hill, May 18.

(Special Correspondence.)—It is reported that the Blazing Star mine, a mile from West Point, is being negotiated. This report has not been confirmed. The Blazing Star at one time was one of the important mines of this county, and has been a large producer of gold. The mine has a complete milling equipment, though now somewhat antiquated.

Negotiations for the sale of the Foltz property are reported to have fallen through. An engineer came here to make an examination on an understanding with the owner, but on his arrival at the mine the owner, like Hopkins, in Mark Twain's 'Gilded Age,' raised the price on the prospective purchaser, and the engineer left in disgust, at least such is the report. The vein in the Foltz mine is 16 or more inches wide and carries payable ore. There is a 3-stamp mill on the property.

West Point, May 18.

PLUMAS COUNTY

The International Smelting Co., controlled by the Guggenheim interests, is planning some big developments in the northern part of this county, according to word which comes from Taylorsville, says the *Plumas Independent*.

The company has most of the promising copper prospects bonded in the vicinity of Taylorsville and Genessee valley, and a great deal of development work is being done on several of the claims. It is stated that at the Five Bears mine, where 15 men have been employed for several months, a fine showing is being made, and that a similar showing is seen at the Iron Dyke copper mine near Taylorsville. Work is also being done on the Copper, Native Son, Austrian Syndicate, and other properties.

It is also reported that the smelting company proposes to develop a large amount of electric power from the waters of Clover creek. It is said that 1000-ft. head can be secured at small expense.

SAN BERNARDINO COUNTY

(Special Correspondence.)—The Mojave Annex Tungsten Mining Co., owning property in the Clark Mountain mining district, and the New York Mountain mining district, in the east part of this county, each adjacent to the Salt Lake railroad, the former near Roach, Nevada, and the latter near Brant, California, has purchased a 20-ton mill-equipment, a part of which has arrived at the property. The management expects to have the mill erected by the latter part of June, on the New York Mountain property. The development of the mine has opened, in addition to the wolframite-bearing vein, a vein of high-grade zinc sulphide and copper ore, 4 to 24 in. wide, being somewhat irregular. The ore carries an average of 9 to 10% copper and 10 to 40% zinc sulphide. The tungsten content is estimated to carry a minimum of 5% tungsten trioxide. Most of the tungsten ore of this district is wolframite, which occurs in crystals and bunches, large and small. Hübnerite also occurs here.

Brant, May 18.

SIERRA COUNTY

(Special Correspondence.)—Driving of a lower tunnel at the Monarch Consolidated mine, near Sierra City, will start in a few days. It is planned to intersect the main orebody 200 ft. below the present workings. From the upper levels good ore is being mined and the mill is running 20 stamps constantly. The property was formerly known as the Lee and for several years has been among the premier gold producers of the county.

The Sierra Mining Corporation is arranging for work at the Shamrock property, adjoining the Sierra Buttes mine. It is intended to drive a main adit approximately 4000 ft., and to install equipment at a cost of \$10,000. The purchase price was \$100,000, of which \$5000 has been paid. Much good ore has been opened near surface, and at depth the owners expect to intersect extensions of orebodies that were worked with profit in the Sierra Buttes. San Francisco people are heavily interested.

Everything is in readiness for extensive hydraulic mining at Howland Flat, St. Louis, Port Wine, and other old camps in Sierra county. The massive dam across Slate creek already has been placed in service and work on a limited scale is going on at several properties. An abundant water supply has been provided, and before the close of summer this field is expected to be producing heavily.

The Kanaka Creek mine, worked near Alleghany by Paul D. Propper of Oakland, and Ambrose Madden, is stated to be developing well. Rich ore was recently found in the shaft, and sinking is progressing.—At the North Fork, between Alleghany and Forest, rich ore is reported to have been found last week.

Downieville, May 22.

COLORADO

BOULDER COUNTY

(Special Correspondence.)—The Mojave-Boulder Tungsten Co. has taken over the Diggs-Clark concentrating-plant in Boulder canyon. The concern has headquarters in New York. It purchased the Bracken group of mines, about 12 months ago, which is one of the best in the district, and has been making a large production. The property is managed by Newton H. Brown.—Buster & Stevens are mining a fine body of tungsten ore in the Barker tract.—Woodring & Dupont, who recently secured the Huron mine at Eldora, have commenced operations.

An advance of approximately 20% in the wages of coal miners of this State will have become effective May 1. About 15,000 miners will receive this increase.

Eldora, May 12.

LAKE COUNTY

(Special Correspondence.)—Within the past week, the discovery of two high-grade veins, one in the Ibex and the other in the Fanny Rawlings, has greatly stimulated activity on Breece hill and has broken the usually uneventful routine of the district with a touch of the excitement that attended similar strikes in the early days. Both of the recent discoveries are in new territory and promise to be important with reference to the future development of the properties, and in the production of free gold. The strike on the Ibex was made by the Burton Leasing Co., operating on the 1000-ft. level of No. 4 shaft in a part of the property that has recently been developed. The high-grade streak was found in a large vein that has been the source of a steady tonnage of gold-bearing ore for several months. Small pockets of free-gold ore had been mined from the vein previous to the strike of last week, when a continuous streak of the metal was exposed. A bunch weighing 18 lb. was extracted during the week, it being the largest pocket that has yet been found. A shipment of 20 sacks of ore has been delivered to the smelter and a second lot is now being taken out.

At the Fanny Rawlings, the discovery of free gold has been made in one of the big fissure veins that extended into the property from the Ibex, where they were productive of millions of dollars worth of gold ore. The high-grade streak in the Fanny was cut a week ago when a pocket containing 10 lb. of visible gold was opened. The vein is believed to continue through the entire claim and its discovery is regarded as the most important development that has taken place in the property during the last five years. The Fanny Rawlings is being operated by a company of lessees composed of West Virginia capitalists and is being managed by R. W. Coates.

The rapidly growing Government demand for manganese and molybdenum is the cause of unprecedented prospecting for ores bearing these metals; and a number of large deposits of molybdenite and manganese-iron have been uncovered and samples of the ores sent to R. D. George, State Geologist, who is in charge of the Government investigation. Immense bodies of molybdenite ore have been found near the head of the Arkansas valley, at Wortman and Climax, and in the old Independence district west of Twin Lakes. The ores, although low-grade, are believed to be of sufficient value to justify mining. Government geologists probably will inspect the deposits during the coming month and development is expected to follow.

New bodies of manganese have been recently uncovered in the Carbonate, Penrose, Grey Eagle, Home Extension, and Nisi Prius, and 100 tons daily is being shipped from the Penrose and Home Extension, 40 tons from the Nisi Prius, and preparations are in progress to begin extracting ore from the Carbonate and Grey Eagle. Another body of manganese will soon be opened for shipping through the Bohn shaft, which is now being re-timbered. An output of 200 tons a day is being maintained from the Star properties, on Carbonate hill, the ore

being a fair grade of manganese-iron. This tonnage is being delivered to the Colorado Fuel & Iron Co.'s works at Pueblo. In addition to these extensive deposits of manganese, other bodies are reported to have been discovered in the district.

Leadville, May 20.

IDAHO

KOOTENAI COUNTY

(Special Correspondence.)—The Commonwealth mines, on Hayden creek, near Hayden lake, were taken over by the Commonwealth Mining Co. in November 1916, after having been in operation for 25 years under various owners. The vein is large—over 80 ft. wide—of which 24 ft. has been stoped on the 200-ft. level, and proved by milling to be of payable grade. The property comprises a group of seven locations. Since the acquisition of the property by the new company from 12 to 18 men have been steadily employed, except during a period when the miners struck for higher pay, when a small crew continued to work, keeping up repairs. The wage question has been satisfactorily adjusted and everything is now in good condition for the season's work. The old workings have been cleaned out, the lower levels unwatered, and re-timbering done where necessary. Sinking was commenced in the shaft, but had not proceeded far when it became evident that increased pumping facilities were necessary, the shaft making 25 gal. per minute. Better ventilation also had to be provided. A pump-station was cut 20 ft. from the shaft; also a tank below the floor of the level, and the reservoir covered with a plank floor. A Fairbanks-Morse duplex pump, with a capacity of 65 gal. per minute, under 200-ft. head, was installed, and connected with the compressed air line. The sinking-pump was repaired and will be used in sinking the shaft to the 400-ft. level, the water being lifted by the sinker to the tank at the station. Drifts north and south on this level are in \$25 ore over a width of 8 ft. It is adjacent to this that the vein carries pay-ore for a width of 24 ft. or more. Raises will be cut to connect levels and good ventilation thus secured. Mining of ore has ceased temporarily, awaiting the completion of ore-bins. In addition to \$40,000 spent in development and equipment, buildings have been erected, machinery overhauled, and a large quantity of supplies put in the warehouse. A wagon-road is being built from the mine two miles to Hayden lake, the old road having been destroyed by floods. It is the intention to sink the shaft to 400 ft., to install a hydraulic air-compressor, and a larger hoisting-engine. A mill will be built when ore has been developed on the 400-ft. level. It is estimated that there are 80,000 tons of ore in sight in the huge outcrop, and an additional \$100,000 worth above the adit-level, and \$60,000 between the adit and the 200-ft. level. Besides this it is believed that a still larger tonnage of valuable ore will be developed between the 200 and 400-ft. levels. Ernest C. Wood is superintendent.

Spokane, May 18.

MICHIGAN

HOUGHTON COUNTY

The Calumet & Hecla Mining Co. reports production for the month of April as follows:

Mines	Copper, lb.	For the year, lb.
Ahmeeek	2,473,495	9,873,069
Allouez	771,253	3,165,640
Calumet & Hecla.....	6,855,514	26,969,059
Centennial	125,403	614,670
Isle Royale	1,282,242	4,806,609
La Salle	247,311	711,893
Osceola	1,516,569	6,078,787
Superior	143,614	858,260
Tamarack	478,519	2,143,565
White Pine	453,261	1,240,681
Total	14,347,181	56,562,233

MONTANA

SILVER BOW COUNTY

The Supreme Court of the United States has decided in favor of the Amalgamated Copper Co. against the Heinze interests in a \$15,000,000 damage suit. The Heinze complaint charged the Amalgamated, with the Rockefeller and Lewisohn interests, with attempting a monopoly of the copper industry in Montana, contrary to the provisions of the Sherman anti-trust law. The suit was begun in New York and decided there against Heinze. The Supreme Court affirms the decision. The decision holds that the Heinzes are merely stockholders of the United Copper Securities Co. and that as such they cannot sue for alleged injuries to the company.

NEVADA

ESMERALDA COUNTY

It is reported that several important discoveries of ore have been made recently in the Goldfield district, and that the outlook for a renewal and continued prosperity is better than for some time past. The introduction of flotation in the mills at Goldfield has opened up a new possibility for the low-grade ores and has stimulated development in no small degree. The Atlanta mine is shipping 50 tons of gold-copper ore daily to the smelters in Salt Lake valley. Some high-grade ore has been found in the Jumbo Extension.

LINCOLN COUNTY

(Special Correspondence.)—The El Dorado canyon district, near Searchlight, continues to claim interest. Four mills are in operation, the little 2-stamp plant of the Lombard-Carnation company having been started a few days ago. Five more stamps will be added shortly. At an approximate depth of 60 ft. a fair tonnage of \$50 ore has been opened.—A hoist has been placed at the Royal Western, and shaft-sinking is proceeding. At a depth of 85 ft. a shoot of sulphide ore, ranging from 10 to 30 in. wide, is exposed, carrying gold and silver.—Six to 18 in. of \$80 ore was recently uncovered near the surface on the Clements claim by Clark Alvord. The claim adjoins the Techatticup mine.—Several properties are being examined in the interest of Salt Lake capitalists.

The mill at the Boss mine, near Goodsprings, has been operating several days on low-grade gold-copper-platinum-silver ore, and it is stated that it is making an excellent extraction. Until the plant has been worked up to a high state of efficiency no attempt will be made to mill the higher-grade ore. Occasional shipments of selected ore are being made to Los Angeles by express. Recent mine work has uncovered large bodies of rich copper-bearing ore. O. J. Fisk is manager.

Searchlight, May 18.

MINERAL COUNTY

The Kentucky Consolidated Mining Co. of Chicago, is erecting a Denver quartz mill and crusher on its property near Sweetwater. The ore will be treated by amalgamation and concentration.

NYE COUNTY

(Special Correspondence.)—Placer mining has been resumed at full capacity by the Round Mountain Co., with water from the reservoir in Jett and Jefferson canyons. It is planned to start work this summer on new dams across Jett and Jefferson creeks and impound sufficient water to insure the continuation of hydraulicking well into October of each year. Arrangements have also been made to handle the boulders and cemented gravel blasted ahead of the giants, which is expected materially to lower operating cost. The company is making a thorough milling-test of its low-grade quartz deposits, in the hope of demonstrating the large reserves of this class of ore to be of profitable character. Richard H. Ernest is superintendent.

Round Mountain, May 21.

(Special Correspondence.)—The Orizaba mine, five miles south-west of Cloverdale, has been taken under lease and option by the General Mines Co., of Reno. W. G. Lovie will have charge of operations. Pumps will be installed, the mine dewatered, and the shaft sunk another 100 ft. Two veins have been opened, carrying silver and gold; the ore is stated to average \$40 per ton. A heavy flow of water has caused considerable trouble in the past.

The General Thomas lead-silver mine, at Lone Mountain, is stated to be developing well. The Nicholas Lettunich lease recently shipped 70 tons of \$60 to \$70 ore to the Murray smelter, Utah. Preparations are being made for work by the owners.

Frederick Bradshaw, general manager for the Tonopah Belmont Co. has returned from an inspection of the Surf Inlet gold mine, in British Columbia, and reports the new mill will be completed in the late summer. With the passing of cold weather mine developments are proceeding more vigorously, and construction of surface buildings is making satisfactory progress. The Belmont company has appropriated \$50,000 from its treasury for purchase of U. S. Government war bonds, an example other Tonopah companies are expected speedily to emulate.

The Tonopah Extension Co. is installing a 400-kilowatt generator and steam-turbine near its Victor shaft to insure a steady delivery of power to the hoist and pumps, making it independent of delays resulting from unsatisfactory electric-power service. Unwatering of the deep levels of the Victor will be rushed and development of the orebody 60 ft. on the 1500-ft. level commenced.

Tonopah, May 23.

STOREY COUNTY

The electric motor to operate the pump in the Combination shaft on the Comstock Lode has arrived and will be placed on the foundations promptly. Pumping will soon begin, and the water will be removed from the shaft below the Sutro-tunnel level for the first time in 30 years.—In the Con. Virginia on the 2700-ft. level, the drift is still in good ore and stopping is continued. The ore is to be worked in the Mexican mill.—The Andes is producing considerable ore from the 350-ft. level.—The Ophir is driving north on a promising vein on the 2700-ft. level.

WHITE PINE COUNTY

The bullion-tax paid by the Nevada Con. Mining Co. for the first quarter of 1917 was \$43,146.33.

(Special Correspondence.)—The Nevada Consolidated company is working at full capacity—about 13,000 tons daily. A day's production was lost last week owing to a wreck on the railroad, when a brake-beam dropped down and ditched 11 cars of ore from the middle of the train, making a bad wreck, the worst in the history of the road.

The new crushing department is expected to be in operation about June 1; this will increase the production 25% or better.

The last annual report of the company shows an increase in the ore reserves of 17,000,000 tons, over and above the production last year; there now being 68,000,000 tons of 1.59% ore in sight. This proves what has often been stated that the Nevada Consolidated property was not a short-lived one, but will still be producing 25 years hence.

The Consolidated Copper Mines (old Giroux) is running about 600 tons daily through the mill, and shipping some high-grade native-copper ore from the old Alpha workings. Mr. Hogan, formerly of Butte, Montana, is in charge at the New Giroux shaft on the west side.

The Ward property, 17 miles south of Ely, is shipping daily by means of two tractors and trailers, 12 tons of ore to the trip.

The Ely Consolidated, of which Sam Levy is president, is shipping a car of lead-silver ore this week from the American shaft.

H. S. Williams is leasing on the Jack Rabbit claim and taking out lead-silver ore. Gilmer Bros., of Salt Lake City, are shipping some copper ore from the Lucky Deposit at the old camp of Aurum, in the north-eastern part of the county.

Shipments of ore are now being made from Hamilton by way of Eureka. The manager of the Pallisade & Eureka Railroad shut-down May 1 rather than haul the mails for Uncle Sam at the contract price, but he found that the State Railroad Commission had something to say concerning this, and was glad to start up again and promises to be good.

The camp of Ely generally is prosperous, much building going on, houses all full, it being hard many nights for strangers to secure a bed; there is always a surplus of men here. It is hard to say why, as a shortage is general in other camps in the State.

Ely, May 18.

(Special Correspondence.)—Ott. F. Heizer, general manager for the Louisiana company, operating the old Tybo mine, reports that they have commenced pumping water from the mine, and this week are shipping ore from the upper levels, and from the dumps. This ore is of a very good grade. They are using the Duplex tractor, four-wheel drive, making a round trip to Tonopah in two days, a distance of 68½ miles, at a cost, including depreciation, of less than \$8 per ton; they haul seven tons to the trip using one trailer. It is believed that this old mine will again make good.

It is a vein in limestone, and is continuous for three miles, generally mineralized wherever opened up. It is said to be an exception to the rule, as the value of the ore increases with depth, being 60% better on the fourth level than on the third.

Ely, May 21.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—About 20,000 oz. of gold-silver bullion was cleaned-up at the Socorro mill for the first half of May. The mill is being run to capacity, treating ore from several of the company's own properties, as well as ores from the Oaks Company.

Driving in the Johnson mine is being done by machine-drills. The ore taken out in development is shipped to the mill.

The Oaks Company has increased its ore shipments on the Maud S. Ore of mill-grade has been opened up in another new place during the week and this property is beginning to take on its old-time activity. The mine has produced nearly \$1,000,000.

Pay-day throughout the district will take place twice a month in the future; this being in accordance with the new State law.

Mogollon, May 22.

OKLAHOMA

COMANCHE COUNTY

The High Five Mining Co. operating in the Lawton-Waco field has been rewarded by its persistent drilling in search for ore. The company began drilling several months ago, and met with small encouragement. Hole after hole was put down with only a small showing of ore in some places, and none at all in others. In the 29th hole, however, the strike was made. At 103 ft. from the surface ore was found and the drill continued in ore to a depth of 257 ft., with ore still in the bottom. Hole No. 30 was drilled and again at 103 ft. from the surface ore was reached and the drill was still in good ore at 202 ft. In this hole the grade of ore is better than that in No. 29, running, it is said, 10% blende. The area will be delimited by drilling. Had the company been discouraged by the repeated failure to find profitable ore in the first 28 holes, the rich strike would not have been made. Now the company proposes to build a mill as soon as materials can be placed on the ground.

OREGON

JOSEPHINE COUNTY

(Special Correspondence.)—A mining deal of considerable importance to the copper industry in southern Oregon was closed at Grants Pass this week, when an option on the 20 claims comprising the Greyback copper group on Greyback mountain, 13 miles east of Selma, in the Waldo district, was signed. The lessee is John Hampshire, the local representative of Twohy Bros. Company, owners of the California-Oregon Coast railroad, which is being operated and built from Grants Pass into the Waldo district. The company has been a large buyer of mines in that district during the past three years, and are the owners of the Queen of Bronze copper mine, and the 100-ton smelter, both located at Takilma, in the Waldo district. Under the terms of the contract development work must be started on a large scale at once. The new owners announce that their first work will be the building of a six-mile road connecting the mine with the road leading up Deer creek from Selma, and the shipment of some of the ore now on the dumps. More than 700 ft. of development has been done on the main vein, opening one of the largest copper-bearing ore-bodies in the district. It lies on the north-south copper lode that extends through the Waldo district, and on down into northern California.

The property has been sold by W. L. Babcock, who has owned and developed the property for 16 years. It is the only property in the State where mining locations on the Oregon & California lands have been litigated through the Supreme Court and the title secured by having the patents to the railroad canceled.

Grants Pass, May 20.

TRANSVAAL

A cablegram has been received from the head office of the Transvaal Gold Mining Estates (Ltd.) advising the results for March as follows: Tons milled, 16,635; estimated value of month's output, £31,515; estimated profit, £7986.

Glynn's Lydenburg (Ltd.) reports the results for March as follows: Tons milled, 4115; estimated value of month's output, £8602; estimated profit, £3757.

The Rand Mines (Ltd.) reports results for March as follows:

	Tons milled	Esti- mated value	Esti- mated Profit
Modderfontein B. Gold Mines, Ltd.	46,500	£96,655	£49,250
New Modderfontein G. M. Co., Ltd.	56,000	124,500	65,703
Rose Deep, Ltd.	61,500	74,744	19,094
Geldenhuys Deep, Ltd.	56,240	70,384	11,079
Nourse Mines, Ltd.	45,000	59,910	10,350
City Deep, Ltd.	66,000	128,719	60,110
Village Deep, Ltd.	49,200	75,816	16,187
Ferreira Deep, Ltd.	49,630	82,529	27,086
Robinson Gold Mining Co., Ltd.	55,300	59,479	18,476
Crown Mines, Ltd.	190,000	233,626	54,725
Durban Roodepoort Deep, Ltd.	29,650	40,217	5,192
			Est. loss
Bantjes Consolidated Mines, Ltd.	23,300	21,289	4,517

The output of diamonds in the Transvaal during 1916 was 615,209 carats, valued at £933,643. Copper ore to the value of £623,872 and tin ore valued at £353,027 was also produced during the year. The gold output of Witwatersrand was £38,107,909, and of other outside districts of the Transvaal was £1,377,025, making a total of £39,484,934.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whanghai province, Chosen, reports for the month of April, total recovery, \$147,345.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

CHARLES BUTTERS is leaving for Chile.

SEELEY W. MUDD was in San Francisco.

JAMES M. HYDE is at Silverton, Colorado.

WALTER H. ALDRICH will be in San Francisco about June 1.

JOHN C. RHOADS has returned to San Francisco from Mendocino county, California.

F. O. BROILI has been appointed field engineer for the State Engineers office of Nevada.

DUNCAN MACVICHIE is investigating mines of the Deep Creek district in western Utah.

A. J. SALE of Los Angeles was in San Francisco, and has gone to Battle Mountain, Nevada.

F. L. SIZER has returned to San Francisco from a visit to the deep gold mines in Amador county.

WILLIAM A. ARGALL has joined the Colorado Field Artillery and is now at Fort Logan, near Denver, Colorado.

HARRY MORRIS, representing the Angels Iron Works, has opened an office at 1206 Hobart building, San Francisco.

CHARLES B. CRONER, of Pasadena, recently examined the Admiral Schley property, near Greenwood, in Eldorado county, for the Los Angeles owners.

E. W. BULLARD, editor of the *Bulletin Board* of San Francisco, has received a commission as Second Lieutenant, and is in the Officers' Reserve training camp at the Presidio.

V. C. SUCKOW, chief inspecting engineer with Falkenburg & Laucks, Seattle, Washington, has received a captain's commission in the Engineers' Corps and has reported for duty at the Presidio at San Francisco.

GEORGE W. BLACKINTON, Denver representative of the Sullivan Machinery Co., has gone to Ft. Riley to take the Officers' Reserve Corps training. M. R. BLISH, of the Chicago office, succeeds Mr. Blackinton in Denver. SIDNEY F. GREELEY, of the Chicago office of the Sullivan company, and also FREDERICK W. COPELAND, son of the president of the Sullivan company, have gone to Ft. Sheridan to take the Officers' Reserve Corps training. Mr. KENNISTON, of the San Francisco office of the Sullivan company, has enlisted in the aviation corps of the army and has gone to San Diego for training.

Obituary

C. C. LEAVITT, who was well known on the Pacific Coast as a mine operator and manager, died at Jerome, Arizona, on May 10. He was for some time superintendent of the Copper King and Fresno copper mines.

ARNOLD HAGUE died on May 14 at Washington. He was one of the most notable geologists of America, belonging to that group of broadly educated and far-seeing men around whom the development of the West has seemed to grow as a vital and undying tribute. He was born in Boston in 1840, and graduated from the Sheffield Scientific School at Yale in 1863. Thence he went abroad, securing the advantages in succession of the Universities of Göttingen, and Heidelberg, and the Freiburg School of Mines. He became assistant geologist under Clarence King, and soon had acquired fame for his abilities, so that his services were in wide demand. His activities covered many countries, and several universities have honored themselves by honoring him with degrees that recognized his fine discriminating scholarship. He was identified with scientific progress in many phases, and has left an indelible impress upon his times.

THE METAL MARKET

METAL PRICES

San Francisco, May 29

Antimony, cents per pound.....	23.50—25.00
Electrolytic copper, cents per pound.....	33
Pig lead, cents per pound.....	10.25—11.50
Platinum, soft and hard metal, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	\$95
Spelter, cents per pound.....	11.50
Tin, cents per pound.....	65
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, May 29

Antimony, 50% metal, per unit.....	\$1.70
Chrome, 40% and over, f.o.b. cars California, cents per unit.....	50—55
Magnetite, crude, per ton.....	\$8.00—12.00
Tungsten, 60% WO ₃ , per unit.....	20.00
Molybdenite, per unit for MoS ₂ contained.....	40.00
Manganese, 45% (under 35% metal not desired), cents, unit.....	36—38

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese.....	Per unit \$1.00
46 to 49% metallic manganese.....	0.98
43 to 46% metallic manganese.....	0.95
40 to 43% metallic manganese.....	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

EASTERN METAL MARKET

(By wire from New York)

May 29.—Copper is firm, with prices nominal at 32.50c. Lead is strong and higher at 11 to 11.25c. Zinc is dull and firm at 9.50c. Platinum is unchanged at \$105 for the soft and \$110 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

The silver market remains narrow and sensitive, and, as has been the case recently, very little buying or selling has an effect on the market totally disproportionate to the amount changing hands. For instance, on April 27, quite a moderate amount of buying caused a rise of 5s.16d., and a few further orders on May 31 were responsible for a similar movement of 3s.8d., and today of 1s.4d.

For the fourth consecutive week there has been a reduction in the amount of silver coin and bullion held in the currency reserve in India. It now amounts to only 1537 lacs, the lowest since November 25, 1913.

The stock in Bombay consists of 1500 bars and is unchanged.

The stock in Shanghai on April 28 consisted of about 26,800,000 oz. in sycee and \$17,400,000, as compared with about 26,500,000 oz. in sycee and \$17,200,000 on April 21, 1917.

The last three Indian currency returns received by cable give details in lacs of rupees as follows:

	April 15	April 22	April 30
Notes in circulation.....	8147	8340	8272
Reserve in silver coin and bullion.....	1674	1629	1537

Quicksilver: On account of very little demand during the past week, the sellers have reduced their quotation to \$105 at New York, though quantities can be had at even a lower figure than this. Foreign quicksilver is offered from \$95 to \$100 according to position. The San Francisco quotation is \$95.

TIN

Prices in New York, in cents per pound.

	1915	1916	1917		1915	1916	1917
Jan.....	34.40	41.76	44.10	July.....	37.38	38.37

June.....	40.26	42.07	Dec.....	38.71	42.55

Platinum is quoted at \$105 for soft unalloyed metal and \$110 for the hard natural platinum-iridium alloy.

According to the British consul at Ekaterinburg, Russia, the 1916 output of platinum in the Urals amounted to 86,500 troy ounces, only about three-fourths of the output in 1915. The chief causes of the decline in the production of platinum are the shortage of labor, the difficulty in obtaining spare parts for dredges, and the exhaustion of the richer alluvial deposits. New alluvium will undoubtedly be found when extensive prospecting is resumed.

Manganese: Manganese is very much in demand and even ore which formerly was not finding a market in New York is now easily absorbed by consumers. Any ore from 36% up, and if of desirable composition, can now be sold. High-grade ore is quoted at \$1 per unit.

Antimony: The antimony market fluctuated very little during the past week. Considerable business has been done at prices ranging from 24½ to 25½c. for early and spot delivery with forward delivery quoted from 16 to 17c. per lb. according to position. Needle antimony is quite firm for spot delivery and 12½c. has been paid. Future ore is quoted at 9 to 9½c. according to month of shipment. Antimony ore has again changed hands at \$2.30 per unit and short ton, and more business is possible at this figure if freight can be obtained from South America.

ORES

Tungsten: Canada is a recent inquirer for both concentrate and the ferro-alloy, the quotations for which are about \$18 to \$20 per unit for 60% ore, and \$2 to \$2.15 per lb. of contained tungsten in the ferro-tungsten. The market is rather quiet as compared with the active one of the past few weeks. The official quotation of \$20 per unit for 60% concentrate is the only one offered by some sellers.

Molybdenum: There seems to be a good demand for the ore but not much offered. The market is quiet at unchanged prices from those formerly quoted.

Eastern Metal Market

New York, May 23.

Strength characterizes the entire metal market, but in general the amount of business really done is not large.

Copper is entirely nominal, especially for the early positions, and transactions are small.

Zinc is firmer with a strong undertone, but the market is very dull.

Lead continues scarce, and any buying forces the market up.

Tin is quieter than last week, but is high and strong.

Antimony is in fair demand and is steady at about the same prices as last week.

Nothing seems to impair the strength of the steel market. Deliveries and mill conditions grow worse instead of better, and capacity is so completely sold up that interest normally in new business is greatly lessened. Foreign inquiries are still very large, but they result in few orders, due to uncertainty as to Government orders and needs. Advances in semi-finished steel show no let-up, sheet-bars having recently sold at \$95 per ton. Large foreign tin-plate sales could be made, but doubt is expressed whether shipments out of the country will long be allowed. A copper price of 24 to 25c. per lb. is not improbable for Government and general war needs.

COPPER

The market could hardly be more nominal than it now is. Metal for delivery this side of August 1 is very hard to obtain, second-hand or re-sale dealers being the only medium. Some business is reported for these deliveries, but it is not large. The quotation for spot delivery is reported by some at 33c., New York, with May and June at 32 to 32.50c., though others quote as low as 31.50c. In the absence of sales of any amount, definite quotations are extremely difficult and entirely nominal. Third-quarter metal is generally quoted at 28.50 to 29.50c., New York, with some business being done. The market is largely a waiting one, pending a definite programme as to the Government's and Allies' needs and purchases. A desire is manifested by consumers to be kept posted as to conditions, but they exhibit little inclination to buy. Attempts on the part of one or two sellers to create an interest in nearby shipments were without satisfactory results. Despite the submarine blockade of our ports since February, exports of copper in the first four months of this year have exceeded any previous four months before or since the War began. With those for April estimated, exports to May 1 of this year have been in excess of 170,000 gross tons, which compares with the best previous four-month record of 152,000 tons early in 1914, when Germany was preparing for the War that began late that year. "Allowing for a submarine loss of 5000 tons per month, the allied governments have received as much American copper since January 1, 1917, as all the foreign countries together took in the corresponding period of 1914." This from the copper sub-committee of the Raw Materials committee of the Council of National Defense, with John D. Ryan, president of the Anaconda Copper Company as its head, is regarded as a bull-argument as to the future and the war purchases.

TIN

The market at present is dull and quiet, but very strong. Fairly good sales were made on May 16, probably 250 tons in all, mostly for spot and nearby shipment, at 66.25c., New York, with about 50 tons sold on the following day, all spot, at 65.25c., New York. Since then the market has been dull with the quotation on May 18 at 65c., New York, for early-delivery metal, with small sales reported. Yesterday and on Monday the market was dull with small sales of nearby metal, and more offered than sold, the settling-price being 65.25c., New York. The quotation yesterday was 65.50c., New York, for early de-

livery. Spot supplies are strongly held and the market is a narrow one. Reasons advanced for the present dullness are that sellers are uncertain as to their future supplies, especially as regards permits from England and the safe arrival after they are afloat. This has caused a decided hesitation. Buyers, on the other hand, are proceeding slowly, and have good reasons for so doing. Most of them are probably well covered, but they do not know where they stand as to the proposed Government tax, one statement being to the effect that the tax will go into effect on the date of the bill. These considerations cause an unsettling condition, and also contribute to hesitation among buyers in general. The London market is still very strong. Yesterday the quotation there for spot Straits was £254 7s.6d. per ton, an increase of £1 7s.6d. over last week, bringing the total advance in two weeks to over £22 per ton. This strength has its influence on the market also. The quantity afloat, to May 21 inclusive, was 3422 tons, with the arrivals for the same period at 3525 tons.

LEAD

Most of last week prices remained stationary but firm, but there has been an advance this week. Yesterday the quotation was 10.87½c., New York, or 10.72½c., St. Louis, as compared with 10.50c. for most of last week. Some metal was sold on Monday, May 21, at 10.75c., New York, and one dealer reports a sale of a carload yesterday at 11.75c., New York. Some producers are attempting to keep the market from advancing, but without success. This week there has been a good demand for prompt and June metal. No liberal sales are reported as having been negotiated quietly. The market's strength rests in the probable Government purchases of large quantities, with the supply possibly insufficient to prevent a decided scarcity. The American Smelting & Refining Co. advanced its price on May 17 from 9.50 to 10c., per lb., New York. The London quotation yesterday for spot lead was £30 10s. and for futures £29 10s. with the market firm.

ZINC

It is very unusual to record that the quotations for spot and May are practically the same as those for June, July, and even third quarter; that futures are as high or higher than early-delivery metal. Such is the interesting and anomalous case today. Sellers and producers are unwilling generally to bind themselves for deliveries much beyond June, and some have refused firm offers at present quotations for third quarter. One or two, however, quote about ¼c. less for third quarter, but report no business. The price has stiffened somewhat in the last day or so after having remained almost stationary for some days. Spot and May or June prime Western is quoted now at 9.25c., St. Louis, or 9.50c., New York, which may also be said to be the price for July or third quarter. There is practically no demand, but the fact that ores are stiff, and that Government buying is bound to be large sooner or later exercises a steadying and firm influence. The needs of the Allies are also figured as likely to be large.

ANTIMONY

There is little change in this metal from the situation last week. The price is about the same for the early delivery of Chinese and Japanese grades, 25 to 26c., New York.

ALUMINUM

Prices are maintained by the present moderate demand because supplies are not large. A report is current to the effect that the United States government has been granted the regular contract price of 37c. per lb. for aluminum by the Aluminum Company of America. Quotations for No. 1 virgin metal, 98 to 99% pure, are unchanged at 59 to 61 cents.

EDITORIAL

T. A. RICKARD, Editor

EIGHTEEN leading copper companies have announced their subscriptions to the Liberty Loan. The total thus subscribed is \$8,500,000. The Anaconda heads the list with a subscription of \$2,500,000, followed by Inspiration and Miami with \$1,000,000 each.

CAPITALIZATION of the new oil companies organized in Wyoming in the first three months of this year, aggregates the modest sum of \$189,175,000! This total has been further increased by large additions since April first. A single company was incorporated with a capital stock of \$10,000,000. So numerous and evidently over-capitalized are most of these concerns that they have attracted the attention of the Federal Government, which is not too busy with preparations for war to ascertain whether the ready money of the public is likely to be as usefully employed in purchasing stock in mushroom oil-companies as if it were invested in Liberty Bonds.

COPPER production today, despite the higher wages paid, and the enormously increased cost of supplies and new equipment, is maintained at a cost per pound equivalent to the average reached seven or eight years ago. For example, the costs per pound during the first quarter of the present year were 10.843 cents at the Utah Copper, 11.02 cents at the Nevada Consolidated, 10.12 cents at Chino, and 11.084 at Ray. These figures represent a marked increase over those prevailing three years ago, yet it is interesting to observe that wholesale mining and milling methods and advances in scientific management have made it possible to produce this metal during a period of war on a par with the best attainable achievements of less than a decade ago when the cost of supplies was 50% below present market quotations.

HIGH-GRADING may have been developed into an art simulating some of the skilful flights of frenzied finance, but the accusation that the United States Mint at San Francisco had purchased \$7,000,000 of such contraband bullion in the last five years, and that the authorities, with childlike simplicity, had recently paid out \$500,000 to unidentified parties, is altogether too saffron-colored a tale to be passed over as a mere vagary of the yellow press. The watchdogs of our national treasury are not behaving in that somnolent manner. The Colorado high-graders have in fact made shipments from time to time to the San Francisco mint, and the result has been investigation leading to arrests. When a man pays expressage on bullion from Colorado to San Francisco instead of taking advantage of the Denver mint, this striking disregard of the fundamental prin-

ciples of economy awakens the suspicions even of an easy-going Federal servant.

TIN-PLATE for cans consists by weight of 2 parts tin and 98 parts steel. The Department of Commerce has just issued a bulletin on this subject, intended to stimulate the production and use of substitutes for 'tin' cans, calling attention to the extraordinary demand for tin containers, exceeding by nearly 40% the consumption last year. If the demand were warranted, it is evident that the shortage would not have been made good in time to save the crops. We explained, however, in a recent issue, that a considerable proportion of the demand that sent the price of tin soaring was due to the fear of small packers that allotments would be made *pro rata*, in consequence of which they called for quantities of cans in large excess over their actual requirements. We pointed out that the scarcity of tin was more apparent than real, and that in our opinion the market would soon reflect the true condition. At a matter of fact the demand for tin promptly discouraged the exorbitant quotations, and our New York correspondent now records an exceedingly dull market, with a decline to 62½ cents. We anticipate still lower figures, indicating that the danger of a serious shortage is past.

INTERESTING statistics of our natural resources have been issued in summary by the Mechanics and Metals National Bank of New York, from which it appears that the national wealth per capita is \$2404, the national indebtedness \$28.80, the money in circulation \$45.60, and the gold money in the country \$26.44. The value of the agricultural output in 1916 was \$73.46 for each person, the copper produced was 23 pounds, while the pig-iron amounted to 760 pounds. The output of raw materials this year will result in perplexing disproportions. Food-stuffs and cotton will be only slightly augmented, but the metals will show an increase that signifies an enormously greater labor-factor that must put an unusual strain upon our capabilities of supplying provisions at prices that will be within the reach of the people. A forecast of the coming stringency may be deduced from the steel trade alone. Orders booked by the United States Steel Corporation at the end of April last year called for 9,829,511 tons of steel; this year the orders on the same date demand an output of 12,183,083 tons. Taking another measure, we find that the railroad earnings on 26 of the largest roads for the second week in May exceeded by \$1,110,507 their net income for the same period in 1916. These few figures, illustrating the sudden growth in volume of those industries that must attract increasing

numbers from the farms, are impressive indicators of the seriousness of the food problem, which has not been as universally credited as the case warrants.

FURNACE-CONSTRUCTION in the Eastern States is so excessive that the demand for refractories is out of all proportion to the supply. Not only is the price of such material advancing by leaps and bounds, but it is becoming generally impossible to obtain the necessary bricks. The manufacturers of such supplies are increasing their equipment with the utmost rapidity. The Pittsburgh Refractories Company is sold out already for over two years, and other companies are in nearly the same position. The American Refractories Company is just completing a new plant at Baltimore, this being the seventh established by that concern, and this single addition will have a capacity of 30,000 magnesite and chrome bricks daily. Active prospecting for these two substances has developed a state of excitement throughout a considerable part of California, in which State magnesite is found in at least 15 counties, and chromite in 26. Imports of chromic iron into the United States increased from 76,455 tons in the year 1915 to 114,655 last year. The present demand will absorb all that can be offered.

CARRANZA has again ruffled the waters of peace. Nothing serious has occurred as yet, but such a cryptic utterance as that in his recent post-prandial remarks hinting darkly that Mexico might be drawn against its will into the world conflict accords with the inferences we have been forced to draw from his feeble protestations of neutrality, accompanied by his recommendation to other Latin-American nations to refrain from shipping supplies to the Entente Allies. Mr. C. W. Barron has intimated through the *Boston News Bureau* that the Mexican officials have suddenly grown polite to Americans on observing Uncle Sam take down his rifle from above the fireplace and load it with real powder and ball, but the most optimistic could hardly anticipate that Carranza would now co-operate with the United States, though it is never too late to show a sense of gratitude for favors done. It is time that the Mexican people should realize that this country does not and never did desire or contemplate annexation of their territory. Our acts throughout the revolution have demonstrated unselfish friendship for the Mexican nation, despite occasional clashes due to some unfortunate misunderstandings.

MAINE was an early mother of copper smelters, as Georgia was the home of the gold miners that laid the foundations of Californian milling practice in the days of Forty-nine. Just across the bay from Mt. Desert, at the old fishing port of Blue Hill, is a once-famous copper mine, where works existed that were notable in their day. The ore was roasted in heaps, and smelted in reverberatories in the early Welsh manner. Here were trained men that later became foremen and managers of copper smelters in the West and that helped to establish

industries so much bigger as to make Blue Hill seem like the play of children. So suddenly was the operation brought to a standstill by superior orders that half-burned ore-heaps were left in the roast-yard, and a full charge of copper, oxidized to the point where it was ready for poling, was left untapped in the refinery. That frozen bath of oxidized copper has been used many times as a lure by promoters seeking to revive the mine. Now comes the American Smelting & Refining Company, which finds in the silicious chalcopyrite ores of this long abandoned mine a needed flux to assist in its smelting operations at Perth Amboy, New Jersey.

SHORTAGE of bottoms has nowhere been more severely felt than in the nitrate trade. Despite the growing need of sodium nitrate the exportation from Chilean ports for the first quarter of this year was only 800,656 tons, being 30,363 tons less than for the same period in 1916. The Department of Commerce announces that it is impossible to secure sufficient nitrate from Chile for use this season, and the Government is able to release only 4000 tons, which cost \$60 per ton at seaboard. The quotations in the open market are \$76 per ton. While no large deposits of nitrates exist in America, the time has come for utilizing the small concentrations that occur in various basins in the arid West, notably in Inyo, Riverside, and San Bernardino counties, in California. Furthermore, the mineral nitrocalcite is much more abundant than is generally known. It is frequently to be found, if searched for, in the seams, joint-planes, and other spaces in limestones in the desert countries underneath what are known as bat-caves. Nitro-glauberite is also found frequently as an efflorescence and as fibrous masses, in the desert bolsones. The prospector is the man above all others to possess information of these occurrences, and this would seem to present an opportunity for the individual to make a little grubstake by collecting nitrates, at the same time helping to make up the deficiency in this needed material. In the aggregate some thousands of tons might be collected from small isolated deposits within the next few months.

MINERAL development is essentially a story of disappointments over-topped by luminous splendors of success. With ceaseless iteration come tales of waning hopes, followed by sudden discoveries of ore just beyond the latest workings. Were not the persistence of the miner greater than the average persistence of the ore when he finds it, the metal output of the world would be immeasurably reduced. A new example comes from the Waco-Lawton zinc district in Oklahoma. The High Five Mining Company entered upon a drilling campaign; hole after hole proved blank, but, with fine determination, those in control would not permit twenty-eight failures to dampen their enthusiasm. The twenty-ninth hole passed through 154 feet of pay-ore and the thirtieth hole confirmed the revelations of its predecessor. It furnishes an interesting object-lesson, not in apology for the 'wild-cat' but in approval of the sane adventurer.

Such exploration is for the man that can afford to lose; it is for him that can play fair toward himself and toward every other party interested in the outcome. One drill-hole, or a half-dozen, cannot be expected to settle the matter. The safety of numbers in deducing a correct average is not there. The owner of property that is deemed worth drilling should protect himself by requiring enough drilling to insure demonstration; the engineer should wash his hands of the enterprise that he may have recommended, unless his clients agree to a sufficient amount of work to prove the ground; the company that is unwilling to venture enough to get the truth had better convert itself into a syndicate for buying Government bonds. The Oklahoman, like the Missourian, was in doubt until the 29th hole showed him something, and he is still uncertain until he has drilled 29 more, and then . . . more!

Potash

Some years ago the United States was content to believe, and even freely acknowledged, that Germany held a world-monopoly in potash, and consequently that our grains and grasses and the greater part of our most nutritious foods were dependent upon the rejuvenation of our soils by this precious alkali, which came exclusively from the mines at Stassfurt. We were also taught to believe that the only possible rival of Stassfurt was the great salt deposit of Kalusz in the Carpathians; but what is Austria's is Germany's, as has abundantly appeared in the sequel, confirming the darkest fears of Metternich. Recently the German technical staff has indulged in jubilant comment upon the crop-shortage in the United States for the season of 1916, attributing it directly to a scarcity of potash. As a matter of fact the diminished harvest last year, and the threatened deficiency in 1917, are the result of inclement weather-conditions in Western areas where fertilizers as yet have scarcely been applied to soils. Nevertheless there is an immediate scarcity of potash, and the price is correspondingly high, with a relatively inactive market. The increase in price from about \$30 per ton for the chloride in normal times to \$400, as now quoted, exerts a restraining influence on the agricultural demand as reflected through the manufacturers of fertilizers. The farmer is content to let the plants starve a little if necessary. It will be seen that, with such high prices for plant-foods, the farmers' investment in a growing crop is enormously increased, and the losses incident to unfavorable weather-conditions become increasingly great, introducing risks that might easily become ruinous. This situation deserves the serious consideration of the Government, and amid the host of other problems neither Congress nor the Departments of Agriculture and Commerce seem to have seriously grappled with the question.

An interesting fact, which should be made clear in order to create a correct public opinion upon this matter, is that we are not necessarily dependent on *Mittel Europa* for potash. Some of the cement-mills of America

are making nearly as much money at this moment out of their by-product recovery of potash as they derive from the cement itself. Every cement works today is becoming a potash factory. The iron blast-furnaces are also preparing to enter the field. Not long ago Mr. R. J. Wysor of the Bethlehem Steel Company made an elaborate investigation into the possibilities of recovering larger quantities of potash than heretofore from the blast-furnace gases. He found that 20% of the original potash content remained in the gases after passing through the scrubber, and furthermore that the larger proportion of the total potash is dissolved and lost in the primary and secondary washers. An average furnace-charge at Bethlehem contains about 22 pounds of potash per ton of pig-iron produced, of which only 20% is carried off in the slag, leaving 80% that may in part be recovered from the gases. Mr. Wysor states that the gases when passed through an experimental Cottrell electric dust-precipitator yielded practically all the potash in the collected precipitate. The saving effected by the same means at the cement factories ranges from 90 to 95% of the potash in the kiln-gases. It thus appears that in Pennsylvania alone, which produces normally ten million tons of pig-iron per annum, assuming a net recoverable 10 pounds of potash for each ton of pig-iron, 50,000 tons of potash might be made available yearly. Ohio would yield half as much on the same basis. In Alabama the outlook is still more remarkable. The so-called 'gray ores' are exceptionally rich in potash, containing over 80 pounds of the alkali per ton of iron on the charge. The additions from coke-ash and flux bring up the total to nearly 100 pounds. Mr. Charles Catlett has estimated that a net recovery of 77 pounds of potash per ton of iron can be obtained in connection with the smelting of these ores. By the installation of the necessary equipment it is evident that the iron industry alone can supply over one-third of our normal demand for potash, obtainable at relatively insignificant cost as a by-product. The cement industry can do as much, so that our survival among the nations of the earth manifestly does not depend upon the favor of Germany. As a matter of fact we have not yet begun to realize upon these resources as we must. In 1916 the total output of by-product potash in the United States was only 8264 tons, with an additional 1550 tons derived from the treatment of kelp. The foregoing figures include molasses distillery waste, which contributed 1845 tons. It is not creditable to the energy and foresight of our people that we should have provided only 5% of our normal consumption of this vital necessary, when 60% at least is immediately available by the application of means that have been developed by Mr. Frederick G. Cottrell and his associates, and proved successful in operation.

Aside from this the production of potash from feldspar has been advanced to the commercial stage within the past few years. The Spar Chemical Company has established works at Baltimore using the Thompson method, in which the feldspar is roasted with salt-cake and common salt, and then extracted, yielding over 80%

of the original potash-content of the rock. The work of Mr. A. S. Cushman and Mr. G. W. Coggeshall has also shown great possibilities, employing no more costly reagents than quicklime and the calcium-chloride waste from the ammonia-soda alkali process. It yields a sludge, which is dried and ground, and that contains above 70% of potassium chloride, equal in quality to the imported German muriates. Furthermore, the search for saline deposits capable of supplying potash has resulted in encouraging discoveries, but the policy of the Interior Department in withdrawing potash lands from entry has not only prevented their immediate utilization, but has completely halted the search for more by private individuals. Reported discoveries are subject to immediate withdrawal until Congress shall have legislated for their disposal. Under a restrictive policy of this nature no relief from that source to overcome our existing shortage of potash is to be anticipated. On April 4 Mr. Thomas J. Walsh of Montana in the Senate introduced a bill that bears the ear-marks of the Gifford Pinchot agitation for conservation, which is so conservative as to stifle all hope for the industry. It provides for the issuance of prospecting permits for a period of three years and covering 2560 acres each. As a reward for discovery it would concede a patent to 160 acres, while any portions of the remaining 2400 acres found to be mineral-bearing would be subject to lease under competitive bids, involving a royalty to the Government on the potash recovered in addition to a fixed rental of fifty cents per acre for the first year, payable in advance, and an annual rental of one dollar per acre thereafter. It happens that the prospector is usually a poor man; at best he is a man of very moderate means, and not likely to be in touch with capitalists under relations that would enable him to arrange in advance for the protection of his interests through a corporation prepared to bid in the leaseholds on ground proved by his exploratory work. It is, in effect, an invitation to undertake the hardships of prospecting chiefly for the benefit of others. This assumes a degree of altruism that does not exist in the average man.

The Germans evidently believe that the want of potash means ultimate starvation. In matters of practical science they have shown such astuteness as to compel respect for this opinion. We are looking forward to the possibility of more than a single year of war, and the winning of that war depends upon ample food as much as it does upon guns and explosives. It would be well to cease fiddling with theories of land location, and pass simple practical legislation recognizing the ancient rights of discovery, so as to get results and get them quickly. The Government experts, working in conjunction with the Council of National Defense may be counted upon to see to it that provision is promptly made to save by-product potash from our blast-furnaces and cement plants, but these will not yield all that we need. If other resources of this important alkali exist on the public lands, Congress has a duty to perform in rendering them immediately available.

Labor Troubles at Jerome

Strikes are out of season. We are at war; our national security, our personal liberties are at stake. The Jerome miners seem to have forgotten that they were trifling with their very liberty of organization, and with their exercise of the other rights of freemen, by undertaking to interfere with the output of copper at the present time. Mr. Robert E. Tally, the assistant general manager for the United Verde Copper Company, definitely charged that the local union had been intimidated by the I. W. W. when it voted for the strike, which indicates that the International Union of Mine, Mill, and Smelter Workers is in exceedingly bad company. With organized labor the whole American public is in sympathy; organized labor is today part of our social system, and it has been recognized recently in a most definite manner by the Congress of the United States in putting the Adamson bill on the statute book, and in a still more substantial form that must be gratifying to every patriotic worker by placing Mr. Samuel Gompers in a high position of trust as a member of the Council of National Defense. At Jerome the really important matter, which was the Miami sliding scale of wages, was conceded by the managers, and the men have returned to work.

Unfortunately, the concession was not made until the discrepancy between the scale at Jerome and that at Miami had provoked unrest—an unrest not at all unnatural, seeing that the ore produced by the two principal mines at Jerome is as rich as the concentrate made at Miami. The opportunity for protest was seized by labor agitators of the less scrupulous kind and was made an excuse for further demands, including the check-off system, the grievance committee, and the closed shop. The management of the United Verde erred in judgment in allowing these contentious points to be raised under cover of the wage-scale. As in most labor troubles the main issue is not evident on the surface; in this case, as in the Morenci strike, the opposition of the mine-managers is directed chiefly against the interference of outside organizations. The strike at Jerome was incited from the headquarters of the I. W. W. at Denver, and if that organization is not as infamous as the Western Federation of Miners it yet has a record and a programme that are repellent to good citizens. A grievance committee of their own men should, and would, be acceptable to the local managements at Jerome, but a committee nominated by an outside organization, frankly devoted to fomenting industrial anarchy, is quite another matter. As to the closed shop, that is too big an issue to be discussed as an incident in the Jerome strike. The refusal to recognize the unions is a matter of established policy in Arizonan mining and the present national crisis is not the time to ventilate it. This is no time for labor controversies. Every good citizen must push contentious matters into the background of his mind and give a willing hand to the greater work that has to be done if civilization is to endure and democracy is not to perish.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Sampling Large Low-Grade Orebodies

The Editor:

Sir—Considerable discussion has taken place from time to time regarding the sampling of large low-grade orebodies, and I am pleased to see the subject dealt with by such eminent engineers as J. H. Mackenzie, D. C. Jackling, and H. C. Perkins. I am sure that a free discussion of this important subject by engineers of such experience will be of considerable benefit to metal mining. Having had some experience in sampling high, medium, and low-grade orebodies both in the United States and abroad, I venture to offer a few remarks dealing with this matter.

You say that one man takes a dozen samples, another a thousand, and a third crushes 100,000 tons of ore. I must say that the first man who takes a dozen samples is likely to be as correct as the man who mills 100,000 tons, as, after all, a dozen samples represent a certain proportion of the ore reserves. I do not pretend to say that a dozen samples should in all cases furnish sufficient data upon which to value a mine; at the same time, I have personally secured options on valuable mining properties without taking a sample, but have thoroughly inspected the assay plans, reports of operation and output-results, in addition to which I have selected duplicate samples and had the same assayed as a check against the assay-office results. This method will fit a case where a mine has been a producer and a good record of ore extraction, ore reduction, sampling, assaying and recording of assays, and results generally, has been kept. Further, this method is as likely to prove correct as if the mine is sampled with moil and hammer. In the examination of a mine the examining engineer is as a rule shown through the workings by some one who points out the best places where good ore has been developed, and it is generally advisable to sample the ore that is said to contain certain values as a quick check against the information given. I often ask the vendor to take a sample of the best ore in the mine simply as a check against the information given; this often saves trouble and expense in sampling, as, if the vendor cannot confirm his own story he cannot expect anyone else to do so. The above is another extreme instance and can only be applied to special cases. The sampling of low-grade orebodies, carrying values ranging between \$2 and \$5 per ton, and expecting accuracy in the determination of ore-reserve value, may lead to disappointment if the sampling by moil and hammer is the only means employed in estimating the value. I may present some details of cases which have come under my personal supervision.

A certain property was taken under option. No great amount of work had been previously done on the property, and what had been done was not recorded, so that it was necessary to start from nothing. The property was 6445 ft. along the strike of the lode-line, which passed over the top of a mountain 1000 ft. high at its greatest elevation. Stations were set 200 ft. apart along the outcrop; trenches were excavated across the lode with pick and shovel, then holes one foot deep were drilled in the hard rock and blasted, thus exposing clean fresh ground. The loose rock was cleaned out and samples cut near the bottom, the width being determined by the formation, that is, the quartz might be 4 ft., schist 3 ft., quartz and schist 5 ft., and so on. These samples were assayed, and an assay-plan prepared by plotting the exact position of the trench, the exact section sampled in feet, the value and the geology. Every sample was thus recorded, and where the first trenches, 200 ft. apart, showed encouraging values a cut was placed between the 200-ft. cuts, and if this latter again confirmed the original cuts then 50-ft. cuts were excavated, and so on, until the cuts over a section showing encouragement were finally narrowed down to 25 ft. apart. Where the original trenches gave no encouragement no intermediate cuts were made, as it was considered unlikely that anything would be found between the 200-ft. cuts. The samples were ordinary samples taken with pick, moil, and hammer and were considered merely as an indication of the probable outline of an orebody or orebodies. Fifteen hundred samples were taken, and 5614 ft. of trenching was made, from which 43,280 cu. ft. of material was removed. The result was so encouraging that an old adit on the vein was cleaned out and extended 2000 ft. into the mountain, the result being that, where values show in the surface cuts, so do values show in the adit at a depth of from 330 to 600 ft. below the surface. A winze has been sunk in one orebody below the adit and levels at 460 ft., and 600 ft. below the surface, confirming the values at the surface.

The determination of the above values was all by the same method, namely, pick, moil, and hammer. Several thousand samples have been taken since, and in order to be sure that the values obtained by sampling could be relied upon there was erected a 3-stamp mill and 18 to 20 tons is being milled daily. Face-samples taken with moil and hammer, car samples, feeder samples, plate tail-samples, and final tail-samples, are all taken as a check on the valuation of the ore reserves. This test is now running and so far it appears to be checking well against the original sampling. I have found that

gold-ore veins, whether high or low-grade, usually carry metal in varying quantities in horizontal planes, the distance between poorer and richer planes being irregular and unreliable. It is a question as to how good the best ore is and how poor the poor ore is, and what proportion one is to the other, that the engineer is confronted with. There are many points to consider when determining the value of an orebody, the nature of which must be ascertained by the man on the spot who must be familiar with local conditions, the particular orebody, and the human side of the question. It is well to remember that sampling by any method or combination of methods is at best only a rough way of furnishing information upon which the valuation of an orebody may be determined.

I have personally sampled orebodies where the average of the samples taken was 52 oz. per ton of ore, and it would have been misleading to have concluded that the orebody would actually average 52 oz. per ton when the same was stoped. The reason for the high average referred to can be accounted for by the fact that the ore contained heavy gold, and it was impossible to sample the orebody without cutting into the material carrying heavy gold. Instead of stoping operations producing an ore valued at \$1000 per ton the average ranged between \$40 and \$50 per ton. Then, again, on a very low-grade undertaking, where the orebody is 48 ft. wide, the average of cut samples with moil and hammer was \$2.75, while the cut and car samples averaged \$2.90. This same vein was re-sampled in 5-ft. cuts taken on alternate sides diagonally, that is, the first 5 ft. was taken measuring from the hanging wall on the north side; the next sample was taken at 10 ft. from the hanging wall on the south side; the next cut at 15 ft. from the hanging wall on the north side, and so on until the full width of the vein had been sampled. Another crew of samplers began by taking their first cut at 5 ft. from the hanging wall on the south side, the second 10 ft. from the hanging wall on the north side, and so on until the whole of the vein had been sampled, the average being \$2.71 as against \$2.75 in the original sampling. A drift 80 ft. in length was extended on the foot-wall of the vein, and the average by cuts and car samples in the original work was \$3.22. This work was checked by samples taken with moil and hammer by one crew of samplers 10 ft. apart, the average of which was \$3.33. Intermediate samples were taken by using a machine-stoper operating a moil; the average of these samples was \$3.37. From the same mine 71,424 tons of ore was milled. The value of this ore based upon underground car-samples was \$3.90 per ton, and the actual recovery, plus tailing loss, was \$3.73, which must be considered a fairly close check on low-grade ore.

In the above details I have tried to show by actual results obtained on mines under my supervision that sampling and determination of values conducted upon the most approved lines, where the sincere object is to guard against unpleasant surprises, was not reliable, and after all only that they formed a basis upon which judgment

could be used in the valuation of an orebody. The valuation of an orebody by cut samples only, without making allowance for errors in sampling or wall-rock being broken beyond the point sampled by moil and hammer, is sure to lead to disappointments, and one way to provide for the low-grade material thus broken is to reduce the value of all abnormally high results from cut samples to what is considered by the engineer in charge the amount to which the cut samples shall be reduced. Here, again, enters the human side of the question, which, in my experience, must always be present. One engineer will continually look for faults and discrepancies and generally do a mine more harm by cautious methods than the engineer who sees no great fault in the mine. At the same time the human equation is always present in both types of individuals, and I believe that, if the particular individual handling the undertaking is thoroughly understood, allowance can be made for the results obtained; and if this can be done the result will be just as satisfactory in the one case as in the other. Personally, I think that an enthusiastic engineer is more likely to find something of importance than an engineer who is of a cautious and unresponsive disposition. I firmly believe that engineers make mines and that mines do not always make engineers. This assertion is in direct opposition to the old saying that a good mine makes a good man. My opinion is that a poor mine makes a better man, and, without a good man, there would be no development of low-grade mines and no occasion, furthermore, for estimating the metal contents of low-grade orebodies.

W. J. LORING.

San Francisco, California, May 9.

The Editor:

Sir—I desire to call attention to an article by L. A. Parsons, re-published in your issue of May 26, which appeared originally in *The Mining Magazine*. Its inception was a contribution of mine entitled 'Latent Errors in Mine Sampling' that appeared in *The Mining Magazine* for February 1915. In that article I described five classes of mines, and endeavored to outline the various complications latent in the ore-structure that tend to vitiate sampling. I will quote part of what I wrote because Mr. Parsons criticizes some of my statements under 'Class 5 by describing his experience in an 'actual case,' which I submit is a type of mine that is not embraced by Class 5 at all, and therefore is irrelevant as a basis of criticism.

The excerpt including the five classes is as follows: "In basing a mine-report on expected output upon sampled areas it should be understood by all concerned that an estimate founded on sampling will remain still an estimate. Irrespective of the experience and care exhibited in the work, the valuing engineer will undertake too much if he assumes that such data embody a statement of fact. The fallibility of an approximation cannot be eliminated, although in cases it may be modified

to meet the necessities of practical requirements. There is a latent error varying with the mineral nature of the ore-structure that it is impossible under practical conditions to control by extreme uniformity in cutting samples and their close adjacency to each other. This error usually indicates a higher metallic content than shown throughout an adequate period of actual ore-treatment, affording data of results in mill-yield, plus residual contents. In the South African banket, the mill-yield plus tailing-content is from 6 to 15% short of the average indicated by sampling. In the premier lead mines of Australia the discrepancy is at least 10%. The results from four well-known gold mines show an unaccounted difference of 12%. These mines are situated respectively in Mexico, Colorado, Australia, and India. In the valuation of a mine, conditions will generally fall under one or more of five classes. After tabulating these as below, I shall endeavor to discuss each in turn. Under practical conditions many of these classes will merge and shade into each other in the same mine; and they are separated here largely to facilitate explanation.

(1) Mines where the average metal-value is mechanically reduced, but where the unaccounted metal may be subsequently recovered.

(2) Mines where there exists an unrecoverable loss.

(3) Mines where sampling indicates a fictitiously high value.

(4) Mines where sampling results in an incorrect sub-normal value, conclusive proof being afforded by subsequent commercial results.

(5) Mines where sampling is of no use."

After dealing with the preceding four classes in further detail I then describe Class 5 as follows: "There is a class of mine where the valuable minerals occur in bunches. Under such conditions no confidence can be placed in an assay map, even although an unusually close sampling-interval may have been employed. A level on a certain horizon may pierce a certain number of enrichments which would be represented on the sampling record. Had the horizon of the level been, however, 30 ft. higher or lower, the number of enrichments pierced in the latter case would be out of all proportion to the former. In a mine of this type an attempt to sample blocked out ore would be absurd. The nature of the ore-occurrence would demand a veritable network of levels and raises so adjacent to each other that all hope of a commercial undertaking would be obliterated by the development-charge per ton. Innumerable cases exist where an assay-plan would show the majority of samples as unprofitable, yet, the commercial result has afforded conclusive proof to the contrary. This class is not composed only of precious-metal mines. The base-metal mines of Missouri and the copper mines of Lake Superior are analogous. The only method of reliable valuation in a deposit of this type would be based on an authentic record of past yield, in combination with competently selected representative shipments of the remaining ore."

Why I state that Mr. Parsons is irrelevantly applying

an 'actual case' in attempting to criticize my observations under this class, is because he devotes about one page to describe the elaborate painstaking manner in which the various mine-openings were sampled. Had such a programme been applied to a mine properly belonging to Class 5 the sampling result would be a series of 'blanks' on a mine that might continue profitable operations for years. The Tightner mine of Alleghany, in my judgment, is an actual case included in Class 5. The ore essentially occurs in bunches, or like 'plums in a pudding.' The success of the undertaking depends on the importance of the 'plums' when found, and their frequency of occurrence, necessary to offset the dead-work entailed in their search and show a profit. For example, one small stope of less than 9 ft. square produced over \$50,000. The vein between the stopes is very low grade, and frequently valueless. In the case of the Tightner mine I am unable to see what would be gained by sampling the intervening spaces. If an engineer did this, and attached any weight to the result, he would probably turn the mine down. In other words, he would commit one of the most difficult mistakes the valuing engineer can live down, namely (assuming the question of price is not entailed), that of turning a good mine down which continues successfully to operate and give the lie to his statements. Also, no tangible object can be gained by sampling one of the 'plums,' which is probably so rich in spectacular gold that more gold is contained in one-half pound of ore, than the average high-grade mine contains in one ton. I therefore submit that there are such mines as I describe under Class 5, and the only competent method of valuation is as that which I attempt to outline.

Value of a Mining Share

The Editor:

Sir—What is it that gives a mining share its market value? Is it the estimated present value of the mine, its potential value, or is it the demand in the market for that particular stock, in case the stock is listed on the Stock Exchange? I have often noticed that the stock of a profitable mine—one that pays dividends regularly—is usually quoted at a price that is evidently considerably above its actual value. Is the market quotation on any mining stock a reliable indication of its real value? To me it seems that it is not so much what a mine has produced in the past as what it can be made to output at a profit in the future that should operate in the public appraisal of the stock.

For a long time I have watched the spectacular rise and fall of Comstock shares, and have observed what to me seems strange, namely, that when a Comstock mine declares a dividend—and they have been known to do so—the stock of that particular mine almost invariably drops a few points. I feel certain that this sudden fall in the market price of shares in a mine under such

auspicious circumstances as the declaration of a dividend is not due to a clear recognition of the fact that the mine has just been depleted of more of its available assets, to the extent of the aforesaid dividend, but must be attributable to some other, perhaps a psychological phenomenon. It is true, a mine that pays a dividend is worth less than before, to the extent at least of the amount of the dividend, but during the time that the ore was being mined that made the dividend possible, work may have been done, resulting in discoveries, the development of which may more than double the visible value of the mine. It is a problem that keeps me guessing.

San Francisco, May 5.

A TIMID INVESTOR.

What Makes a Good Flotation Oil?

The Editor:

Sir—I have read with interest the papers on flotation, published from time to time in the MINING AND SCIENTIFIC PRESS, and the opinions it seems permissible to form therefrom are: (1) a mineral with a metallic lustre adheres better to an oiled film than does quartz; (2) air adheres more firmly to a mineral with a metallic lustre than to quartz; (3) the difference of potential between a sulphide-particle and an oiled film is greater than that between a quartz particle and an oiled film; (4) oil makes the film enclosing the air-bubble stronger; (5) the continuous formation of bubbles lifts the oiled solids over the lip of the flotation cell. There appears to be need of a diagram illustrating the difference of potential between the mineral to be recovered and the various mixtures of the flotation-oils most readily available. Any application of physical force to a solid makes it more electro-positive. Hence in the emulsifier of a flotation machine the mutual bombardments of the solid particles impart to them an energy which manifests itself in an increased attraction, however slight, between the solids and the oiled film. The five causes of concentration by flotation mentioned above are the most important, and of these No. 3 and 4 demand the most attention, but in the phenomenon of flotation the degree of fineness of the solid particles in the pulp has also a bearing from the point of view of the grade of the concentrate. Finely ground gangue will be floated with the sulphides. Where the smelter is adjacent to the mill the grade can lie within fairly wide limits, but where transportation charges are a serious factor the grade is of greater importance than the percentage of recovery. For instance, in a South American mill with which I was at one time connected no ores assaying less than 18% copper could be handled profitably before the outbreak of the War, and even with the recent high prices this minimum percentage could be reduced only to 11%. Where a high-grade concentrate is required, I presume that an oil, or a mixture of oils, would be used, which would produce not too profuse and tenacious a froth, and which would have the greatest potential difference. With a feed assaying about 1% copper a certain recovery is effected; with 1.25% copper a higher recovery and a cleaner concentrate is

made when the amount of oil added and the volume of air used remain constant. The electrical charges may be represented as follows: the air-bubble —, the quartz +, and the sulphide particle + +. Then, in the case of the richer pulp, as the film becomes more heavily coated with sulphide particles the difference in potential between the quartz and the film will become less, and therefore the tendency for a cleaner separation would become greater. Secondly, as the bubbles are stronger, fewer of the sulphide particles that have once been picked up are dropped. If the difference of potential and the strength of the film-diagrams in a series of two oils were once established, and if at the same time the percentage of recovery were experimentally determined in each case for any sulphide-ore, some light would be thrown on the relationship between these factors in 3 and 4. A research on these lines would be of practical value. A paper, if I remember correctly, had the title 'Why is Flotation.' I should be glad to know just 'Why is a good flotation oil'? Should some of the views I have mentioned be incorrect, I would welcome criticism and correction.

McGill, Nevada, May 4.

PAUL T. BRUHL.

Home-Made Mine-Haulage Motor

The Editor:

Sir—At the Sinker tunnel, a 7000-ft. adit in Owyhee county, Idaho, the foreman, T. D. Babbit, has constructed a haulage motor, a description of which might suggest to others a utilization of other discarded power-units. An old Detroit electric runabout was purchased, and its 20-hp. motor, control-device, and 60 Edison storage-cells removed and installed in a frame cast to standard shape for storage-battery motors. Power is delivered from the motor by means of chain-belts passing over pinions on the ends of the motor-shaft to cog-wheels on each wheel. The latter are spaced about 3½ ft. centres, and the frame is 10 ft. long. On one end of the frame is a platform for the operator, with the motor-control and handbrake lever within easy reach. The lamps of the runabout are used for headlights. The storage-cells are on top of the frame, and protected by a wooden housing provided with slots for ventilation. The cost complete was \$1300, including a mercury-lamp rectifier for charging. It hauls 14 loaded cars, each of 18 cu. ft. capacity, at a speed of 6 to 8 miles per hour. The cost for power delivered at the mine transformer is about 2c. per kw-hr., and the power-charge against the motor is about \$6 for 150 ft. of tunnel-advance.

Boise, Idaho, May 17.

A. E. ROBINSON.

MINING in open-cuts is the least expensive of all methods of mining. Where shoveling is necessary, the cost of loading cars should not exceed 20 cents per ton with wages at \$2.75 per shift of 8 hours. Where the broken ore can be passed through a grizzly to a chute to be drawn off into cars below, the limit of economy is reached.

Notes on Compression and Transmission of Air

By ROBERT S. LEWIS

Air-compressors are rated by manufacturers on the basis of piston displacement, or volume swept through by the piston, expressed in cubic feet of free air (air under atmospheric conditions of pressure and temperature) per minute. If compressors delivered this quantity of free air as compressed air such a rating would be satisfactory, but various factors modify the intake-capacity of a compressor so that it may be much less than the piston displacement. The ratio of the free air taken into the cylinder to the piston displacement is called volumetric efficiency, and may be expressed in the form of the equation:

$$(1) \quad E_v = \frac{\text{cu. ft. of free air taken into compressor}}{\text{displacement of compressor in cu. ft.}}$$

The important factors which modify volumetric efficiency are clearance, volume of the piston rod, heating of the air before compressing, leakage of air past the piston and also intake and discharge valves, too small area of valves and the wrong operation of mechanically controlled valves.

The space between the piston, when at the end of its stroke, and the head of the cylinder is filled with compressed air which cannot be discharged. During the return stroke this air must expand until it is at atmospheric pressure before any free air can be drawn into the cylinder. If this clearance space is large, the free-air intake-capacity of the cylinder is materially reduced. In well designed single-stage compressors clearance, expressed as a percentage of the displacement per stroke, is not far from 1% for the large sizes and may be 2% or more for the small sizes of compressors. This means that for a low clearance-value the distance between the piston at the end of its stroke and the cylinder head is only 1/16 or even 1/20 of an inch. The effect of clearance increases as the ratio of compression (final absolute pressure to initial absolute pressure) becomes greater. For large ratios the piston must travel a considerable part of its stroke before any free air can be drawn into the cylinder. If it were possible to compress to 5000 lb. per sq. in. in a single cylinder no air would be taken in during the return stroke. The air in the clearance space, when expanded to atmospheric pressure, would completely fill the cylinder. Assuming that this clearance-air expands isothermally, which is probably more nearly correct than if it is considered to expand adiabatically, the effect of clearance may be calculated as follows:

Let E_c = volumetric efficiency depending upon clearance.

C = clearance expressed as a decimal.

r = ratio of compression = $\frac{P}{P_a}$, P being final absolute pressure in pounds per square inch, and

P_a being the initial absolute pressure. (Absolute pressure is gauge-pressure plus atmospheric pressure.)

$$(2) \quad \text{Then } E_c = 1 + C(1 - r)$$

Thus, when compressing from an atmospheric pressure of 14.7 lb. to 100 lb. as shown on the gauge, with clearance = 2%, then $r = \frac{100 + 14.7}{14.7} = 7.8$, and $E_c = 1 + 0.02(-6.8) = 0.864 = 86.4\%$. In case the clearance of a compressor is not known, it can often be determined by measuring the volume of water required to fill the clearance-space. The effect of clearance upon volumetric efficiency is lessened by using stage-compression. Since the air is not compressed to the final pressure in a single cylinder, the percentage of the volume of the low-pressure cylinder occupied by the expanded clearance-air is reduced. The piston rod occupies space on one side only of the piston, consequently the displacement per revolution, corrected for clearance, less the volume of the piston rod, will give the free-air intake-capacity of the compressor per revolution.

Under constant pressure, the volume of a given weight of air is proportional to its absolute temperature ($460 + F^\circ$). At 60°F ., a given volume of air will expand 1/520th of its volume at this temperature for each degree Fahrenheit rise in temperature. If one cubic foot of air at 60°F . is heated to 100°F . as it enters the compressor its volume will be increased 40/520ths, or approximately 8%. In other words a cubic foot of air at 100°F . is equivalent to 92% of a cubic foot of air at 60°F . The power required for compressing a cubic foot of air, once it is in the cylinder, is independent of the temperature of the air. This means that the colder the air is when taken into the cylinder the less will be the number of cubic feet required to give a desired result. For this reason care should be taken to get the air into the cylinder at as low a temperature as possible. The intake-conduit for the compressor should be made of a non-conducting material, such as wood, brick, or concrete, and should draw air from the coolest place available, never from the compressor-room itself. The cross-sectional area of the conduit should be equal to at least one-half the area of the piston in order that the air can flow freely without obstruction. In hot and dusty localities it has been found beneficial to draw air from the interior of a framework covered with burlap or sacking, which is continuously drenched by a spray of water. This procedure not only cools the air, but removes the dust at the same time.

If a compressor has poorly designed intake-passages, the air as it enters the cylinder may be at a temperature several degrees above that of the atmosphere. The metal

of the cylinder becomes quite hot after a compressor has been running for an hour or more, and, after traveling through long and narrow intake-passages, the air may be heated to 100°F. or above.

Let T_c = absolute temperature of the air after entering the cylinder, and T_a = atmospheric absolute temperature, then

$$(3) \quad E_v = E_c \frac{T_a}{T_c}$$

This is the expression for volumetric efficiency modified by clearance and heating of the intake-air.

Leakage past valves and piston will further reduce the intake-capacity of a compressor. If the area of the intake-valves is too small the cylinder will not be filled with air under atmospheric pressure, and, if the area of the discharge valves is too small, all the air will not be discharged. Poppet valves depend upon a difference in pressure on the two sides of from 3 to 5 oz. for their action, and may reduce volumetric efficiency by as much as 2 to 4%. Mechanically operated valves of the Corliss type are very satisfactory, but they must be maintained in correct adjustment. Though the effect of clearance, and of heating the air before compressing, can be calculated by the formulas it is well to bear in mind that the results so found may not always agree with the actual conditions of operation. The leakage of air past valves and piston, the choking of air-passages, and bad valve-action, are variables that cannot be determined by formulas. Volumetric efficiency is most accurately computed by measuring the air delivered and comparing it with the displacement of the compressor. Such a method includes all factors affecting the performance of the machine.

When the ratio of compression is large the final temperature of the air in the cylinder may be very high. The relation of temperature to volume and pressure is given in the following equation:

$$(4) \quad T_2 = T_1 \left(\frac{V_1}{V_2} \right)^{n-1}$$

$$(5) \quad T_2 = T_1 \left(\frac{P_2}{P_1} \right)^{\frac{n-1}{n}}$$

The subscripts 1 and 2 indicate initial and final conditions respectively. P and T are in terms of absolute pressure and temperature. Volumes V are in cubic feet. The value of n for perfect adiabatic compression is 1.406. For an initial temperature of 60°F., a final gauge pressure of 100 lb., and atmospheric pressure of 14.7 lb., the final temperature of the air would be

$$T = (460 + 60) \left[\frac{14.7 + 100}{14.7} \right]^{0.29} = 520(7.8)^{0.29} = 931^\circ \text{ abs.} = 471^\circ \text{ F.}$$

Should some of the hot compressed air leak back into the cylinder, or should the ratio of compression be increased by throttling of the intake-air through sticking of the valves, the temperature may be even higher than the above theoretical value. That such high temperatures are reached in practice is shown by the explosions that occasionally take place in compressors and receivers. An air cylinder, unlike a steam cylinder, re-

quires only a small quantity of oil, a drop once in four or five minutes should ordinarily be sufficient. The use of too much oil causes an accumulation of carbon that may choke the valves and passages. Kerosene, often employed for cleaning valves, has a flash point of 150°F. or less, and ordinary lubricating oils have flash points varying from 330° to 425°F. In view of the high temperatures that may be reached in the cylinder, such oils are obviously a source of danger. Only a thin air cylinder oil, with a flash point of 600° to 630°F., should be used. For cleaning valves, a mixture of soft soap and water should be fed through the lubricating cups once or twice a week. As a safety measure, it is advisable to place a thermometer or fusible plug in the discharge pipe, and as near the compressor as possible.

For pressures up to 75 lb. per sq. in. single-stage compression is satisfactory, but for pressures from 75 to 150 lb., which are commonly used in mining work, two-stage compression is preferable. The ratio of compression in a cylinder of a two-stage compressor is equal to the square root of the ratio of compression in a single-stage compressor delivering air at the same final pressure; consequently losses in capacity due to clearance and leakage are materially lessened. The inter-cooler of a two-stage compressor will reduce the temperature of the heated air from the low-pressure cylinder nearly to that of the atmosphere before it enters the high-pressure cylinder; therefore the final temperature of the air is lower than for single-stage compression, and lubrication is facilitated. However, the sticking of valves, or the choking of passages, may cause such a high temperature to be reached in the high-pressure cylinder that an explosion will occur, even in a compound compressor.

The theoretical work of compression may be easily calculated with the aid of chart No. 1, constructed by the Nordberg Manufacturing Company.

Curve *a* is for isothermal or ideal compression.

Curve *b* is for three-stage compression.

Curve *c* is for two-stage compression.

Curve *d* is for single-stage or adiabatic compression.

First compute the ratio of compression. Find this figure on the bottom scale and project vertically to intersect the curve for the given method of compression. From this point pass to the left margin and find the horse-power required per pound of atmospheric pressure. Multiply this figure by the atmospheric pressure, and the result will be the theoretical horse-power required to compress 100 cu. ft. of free air. What is the horse-power required for compressing 500 cu. ft. free air from 11 lb. atmospheric pressure to 110 lb. gauge-pressure, two-stage compression? Here $r = \frac{(110 + 11)}{11} = 11$, and

for curve *c* the air horse-power is 1.25. Multiplied by the atmospheric pressure of 11 lb. this gives 13.75 hp. for 100 cu. ft. free air, or 68.75 hp. for 500 cu. ft. The advantage of this chart lies in the fact that it is applicable to compression at any altitude. The actual horse-power required will be slightly less than that given by the chart for adiabatic or single-stage compression.

and a little greater than that given for two and three-stage work. Full adiabatic compression, or compression with no loss or gain of heat from any outside source, cannot be attained in practice because compressors are water-jacketed and have some cooling effect on the air. The inter-cooler used in stage-compression should cool the air to the temperature of the atmosphere, but this efficiency is not reached. Atmospheric pressure varies with the altitude at which it is measured. Its value at

sea-level equivalent to a cubic foot of air at the given altitude is $\frac{P_a}{P_s}$. For an elevation of 8000 ft. this ratio is $\frac{11}{14.7} = 75\%$. This means that every cubic foot of air at

11 lb. pressure is equivalent to only 0.75 cu. ft. of air at sea-level. Since a compressor, operating at a high altitude, will deliver less air than if operating at sea-level, its power-consumption must be less, but power-consump-

any elevation may be found by either of the following equations:

$$(6) \quad \log P_a = 1.1673 - \frac{h}{122.4 T}$$

$$(7) \quad P_a = 0.4931B(1 - 0.0001(F - 32))$$

Where h = altitude in feet.

T = absolute atmospheric temperature ($460 + F^\circ$).

P_a = atmospheric pressure, pounds per square inch.

F = Fahrenheit temperature in degrees.

B = barometer in inches.

Thus for an elevation of 8000 ft. and a temperature of $60^\circ F$., $\log P_a = 1.1673 - \frac{8000}{122.4(520)} = 1.1673 - 0.1257 = 1.0416$, or the log of 11 as the nearest number.

The effect of lessened atmospheric pressure on a compressor is to reduce the quantity of air delivered, as compared with operation at sea-level. With constant temperature the volume of a definite weight of air varies with the absolute pressure. If P_a = absolute (atmospheric) pressure at sea-level = 14.7, the percentage at

tion does not fall off as rapidly as the capacity is reduced. The ratio of compression for 100-lb. gauge at 8000 ft. elevation is $\frac{(100 + 11)}{11} = 10.1$, as against 7.8 at sea-level. A greater ratio of compression means a higher final temperature for the air in the cylinder, and this requires more power for compressing. The heated air tends to expand and thereby offers greater resistance to the piston. At an elevation of 15,000 ft. the reduction in capacity, when compared with conditions at sea-level, is about 42%, but the decrease in power required is only about 25%.

The weight of a cubic foot of air at any pressure and temperature can be found by means of the formulas given below.

$$(8) \quad w = 2.708 \left(\frac{P}{T} \right)$$

$$(9) \quad w = 1.325 \left(\frac{B}{T} \right)$$

where w = weight of air in pounds per cubic foot.

P = absolute pressure.

T = absolute temperature.

B = barometer in inches.

The weight of a cubic foot of air at sea-level and 60°
 $F. = 2.708 \left(\frac{14.7}{520} \right) = 0.0766$ lb., and at 8000 ft. elevation
 $= 2.708 \left(\frac{11}{520} \right) = 0.0572$ pounds.

When calculating the free-air requirements of rock-drills, it is necessary to reduce quantities to equivalent cubic feet of free air at sea-level, a figure usually given by manufacturers in their catalogues. For drills operating at sea-level, but under different pressures, the ratio of the cubic foot of free air consumed would be equal to the ratio of the final absolute pressures used. Thus, for a drill consuming 80 cu. ft. of free air at 90-lb. gauge, the final absolute pressure is 104.7 lb., and for a similar drill operating at 100-lb. gauge, the final absolute pressure is 114.7 lb., and the ratio of two is $\frac{114.7}{104.7} = 1.19$. The second drill requires $80 \times 1.19 = 95.2$ cu. ft. free air. In case it is desired to determine the free-air consumption of a drill operating at 90-lb. gauge and at an elevation of 8000 ft. use the equation.

$$(10) \quad R = \frac{p_a(P_a + P_g)}{P_a(p_a + p_g)}$$

where R is the ratio of free-air consumption at a given altitude to that at sea-level. The small letters are for sea-level conditions, the capitals are for conditions at any elevation, and the subscripts are for atmospheric and gauge-pressures respectively. For the first drill mentioned above, $R = \frac{14.7(11 + 90)}{11(14.7 + 90)} = 1.19 \times 80 = 103.2$ cu. ft. of free air required at 8000 ft. elevation to equal 80 cu. ft. at sea-level.

An all too common cause of loss of power in the use of compressed air is caused by the installation of pipe-lines of too small a diameter. Even though the main air-line may be large enough, the branch lines and pipes to the drills are often so small that a 10 to 25% loss in power is experienced. In order to keep friction-losses within a reasonable limit, the velocity of the air should not exceed 20 to 25 ft. per second. If a 3-in. piston-drill were supplied with air through a 1-in. pipe, the velocity of the air would be over 50 ft. per second, and the resultant drop in pressure would be nearly 10 lb. for a 100-ft. length of pipe. On the other hand as an example, two drills were supplied with air through a pipe-line 10,000 ft. long in which the velocity of the air was only 3.5 ft. per second. The total drop in pressure was only 0.002 lb. Chart No. 2 shows the loss in pounds for 100 ft. of pipe when conveying air at 90-lb. gauge-pressure through small pipes. Evidently it is better to use a $1\frac{1}{2}$ -in. or a $1\frac{3}{4}$ -in. pipe than the 1-in. which is often installed. In Vol. 44, Trans. A. I. M. E. (1913), Nathaniel Herz gives a graphic solution of D'Arcy's formula for computing the size of air lines.

$$(11) \quad V = c \sqrt{\frac{d^5(p_1 - p_2)}{wL}}$$

V = cubic feet compressed air delivered at final pressure.

c = experimental coefficient.

d = diameter of pipe in inches.

L = length of pipe in feet.

w = weight in pounds per cubic foot of air at pressure p_1 .

p_1 and p_2 = initial and final gauge-pressures respectively.

TABLE OF VALUES OF C

Size of pipe	Value of c	Size of pipe	Value of c
1-in.....	45.3	7-in.....	60.3
2-in.....	52.6	8-in.....	60.7
3-in.....	56.5	9-in.....	61.0
4-in.....	58.0	10-in.....	61.2
5-in.....	59.0	11-in.....	61.8
6-in.....	59.8	12-in.....	62.0

Chart No. 3 gives a graphic solution of this formula. To use the chart, find on the left hand margin the quantity of compressed air to be delivered, then pass horizontally to the diagonal line for the length of pipe-line, project vertically to intersect the diagonal for the initial gauge-pressure, then across horizontally to the right to the heavy vertical line upon which the initial gauge-pressures are printed. Use this point as a pivot, and swing a straight-edge to cut the lines for size of pipe and the drop in pressure. The pressure-drop in various sizes of pipes can thus be quickly ascertained. The cubic feet of compressed air to be delivered is found by dividing the cubic feet of free air required by the ratio of the final absolute pressure in the pipe to the atmospheric pressure. If the drop in pressure is large, it may be advisable to re-calculate the cubic feet of compressed air delivered. The method of using the chart may be reversed to find the maximum volume of air that may be handled in a given line.

In order to have a number of branch lines equal in carrying capacity to a main line, it has been found that the pipes should be to each other as the square root of the fifth power of their diameters.

RELATIVE CARRYING CAPACITIES OF PIPES

Size	1	1 1/4	1 1/2	2	2 1/2	3	3 1/2	4	4 1/2	5	6

10	8.3	6.3	3.9
12	10.3	6.3

The efficiency of a well designed pipe-line may be seriously diminished by leaks. Compressed air, under as low a pressure as 13-lb. gauge, will escape into the atmosphere with a velocity of over 1000 ft. per second, and seemingly small leaks will often cause a serious loss of air. At one mine it was found that the compressor-installation was apparently inadequate for the work required. Before ordering more compressors the pipe-lines were carefully examined and all leaks were stopped. The surprising fact was developed that more than 500

hp. had been saved by repairing the air-lines, and the compressors in use could easily meet the legitimate demand made upon them.

When pipe-lines are being constructed care should be taken that white lead or other cementing material is not used in such excess that it is forced into the pipe, thereby obstructing the passage of the air. All joints should be tightly screwed together, and blow-off or drain-valves should be placed at low points so that accumulated water can be drawn off. A pipe-line can be put together so that no noticeable leakage will occur. One of the longest lines in the world, 120 miles in length, is said to have been perfectly tight under a pressure of 600 pounds.

Loss of power is not synonymous with loss of pressure. Where there is a decrease in pressure there is an increase in volume, and the resultant power-loss is less

CHART No. 1

than the loss of pressure. Since the air in a transmission line is at atmospheric temperature, the assumption that it will expand according to isothermal laws is justifiable. The power in the air entering the pipe is therefore $P_1 V_1 \log_e r$, and at the end of the line it is $P_2 V_2 \log_e r_2$, and the efficiency of the transmission of power equals the ratio of the two quantities. Now $P_1 V_1 = P_2 V_2$ and, together with the base e , can be eliminated from the expression. The efficiency of transmission is then

$$(12) \quad E = \frac{\log r_2}{\log r_1}$$

where r_2 and r_1 are the ratios of compression at the discharge and intake-ends of the pipe respectively.

Example: what diameter should be used for a line that is to transmit 4000 cu. ft. free air per minute, com-

pressed to 90-lb. gauge, with a loss of not more than 5% of its energy, atmospheric pressure being 13 lb. and the line being 1200 ft. long? Here, $E = 95\%$ and $r_1 = 7.9$. $\log r_2 = 0.95 \times \log 7.9 = 0.852745$, or $r_2 = 7.1$. Final pressure is therefore $13 \times 7.1 = 92.3$ lb. absolute - 13 = 79.3 lb. gauge, and the drop in pressure is 10.7 lb. The cubic feet at final pressure = $\frac{4000}{7.1} = 564$, and from chart No. 3 the size of pipe to be used is 5½ in., or a 6-in. line.

The cubic feet of free air required by various sizes of

CHART No. 2

rock-drills is given in the accompanying table. The figures represent good average practice.

Cubic feet of free air required by piston-drills at sea-level. Pressure, 90 lb. gauge.

Size of drill, in....	2	2½	2½	2½	3	3½	3½	3½	4½	5
Cu. ft. per minute...	70	87	95	118	126	140	152	160	210	250

Hammer-drills require from 15 cu. ft. for light work, such as hitch-cutting, to 65 or 80 cu. ft. for the large sizes. In a mine using a large number of drills, all the drills are never running at the same time. A factor for estimating the number of drills that would probably be in operation at the same time is as follows:

Number drills...	2	3	4	5	6	7	8	9	10
Factor	1.8	2.7	3.4	4.1	4.8	5.5	6.1	6.7	7.3
Number drills.....	11	12	15	20	25	30	35	40	
Factor	7.8	8.4	10.3	12.8	15.1	17.3	19.7	22	

The air-requirements of different drills vary so that it is advisable to have some means of measuring the air actually used. A simple and sufficiently accurate method of determining the cubic feet consumed is to use two steel tanks from 2 to 3 ft. in diameter and from 4 to 6 ft. high. The tanks are placed close together, and the bottoms are connected by a 3 or 4-in. pipe. A pipe is run from the top of each tank to a four-way valve, which is also connected to the air-main and to the line running to the drills. A water-glass should be placed on the outside of each tank. Marks should be placed on these glasses at the top and bottom so that the tanks can be filled and emptied to these marks and the volume, in cubic feet, required to do this can be calculated. Both tanks should be provided with pressure-gauges. To use the tanks, first fill them half full of water. Air from the supply-line is then admitted through the four-way valve until the water in one tank is lowered to the bottom mark; the other tank is then full of water. The valve is now reversed and air is admitted to the second tank, forcing water into the first one and displacing the air contained, which goes out through the valve to the drills. The cubic feet of compressed air required can be calculated from the number of times the tanks are filled and emptied. The equivalent cubic feet of free air can be determined from the equation $v = \frac{PV}{P}$, where v is the required volume of free air, p is atmospheric pressure, P equals absolute pressure in tanks, and V is the volume of compressed air handled.

Method for Treating Impure Tungsten Ore

By WILL BAUGHMAN

A year ago practically any kind of tungsten ore found a ready market. This so stimulated the search for tungsten deposits that the supply soon responded to the demand, and the old requirements of a high percentage of tungsten tri-oxide and freedom from impurities were re-established. Certain Arizonan and Bolivian wolframite concentrates contain elements that are considered objectionable by tungsten ore buyers. Both of these concentrates also contain considerable silver. I supervised extensive experiments in chloridizing roasting and then leaching the concentrate to extract the silver with thio-sulphate solution. These experiments were fairly successful, but the tungsten residue was still penalized \$2 per unit. Such a deduction means \$120 per ton of concentrate, therefore the removal of the impurities is to be desired. I finally worked out a successful method of procedure. It was positive in action and few impurities can follow through, as is the case with any alkali-fusion process. Furthermore, the impurities are recovered in a commercial form.

The equipment consists of a stoneware digester, two gas-fired evaporators, and ammonia-vapor condenser, storage tanks for ammonia, acid, and brine, two stoneware injectors, an absorption tower, and a retort used in

the regeneration of acid. The process as applied to the Bolivian concentrate, which is very impure, is as follows: The concentrate is digested in strong hydrochloric acid, containing a little nitric. Steam is used for heating and agitation. The period of treatment generally lasts 4 hr. or until most of the iron and manganese are dissolved. The acid solution is filtered off, and should any gold or bismuth be present, as is the case with some Arizonan ores, hydrogen sulphide is passed through to precipitate them. The solution is then evaporated and solid ferrous chloride is charged into the retort where it is heated in the presence of steam and air, converting the manganese and iron into oxides and evolving hydrochloric and nitric acid vapors. These vapors are caught in a vitrified pipe absorption-tower filled with coke. The tower-solution is kept in constant circulation by a stoneware injector. The tower-sump also acts as a solution-storage tank. About 75% of the hydrochloric and 50% of the nitric acid are regenerated. Additional acid is added to keep the solution as it accumulates up to the required standard.

The ore is next leached with a strong hot salt-brine. This brine is sufficiently heated by the steam that operates the injector used for elevating the brine from its storage-tank to the digester. The brine dissolves the silver in the ore. The solution is then run through precipitation-boxes of identical design with those used in cyaniding. Iron scrap and turnings are used for precipitation of the silver. From the precipitation-boxes the solution runs to the storage-vat.

The residue in the digester is next thoroughly washed with hot water which is run to waste. Next the residue is digested with ammonia for dissolving the tungsten tri-oxide. This liquor is evaporated, the ammonia-vapor being led to the condenser and recovered. When all the free ammonia is boiled off the cover is removed, and as the ammonium tungstate crystallizes out of the concentrated solution it is dipped up. This ammonium tungstate is over 99% pure, and is a commercial product.

The residue in the digester consists of silica, tantalite, cassiterite, and some undecomposed wolframite. About 100 lb. of residue remains when treating Bolivian concentrate. It is worked up in the laboratory according to standard methods for recovery of tantalum and tin compounds.

This process is not adaptable to the treatment of a large tonnage, nor would it be suitable for treating high-grade ore. Its field is properly the treatment of impure ore. The tungsten tri-oxide, being 99% pure, brings a higher price than the same amount would bring if combined with other substances. A recent number of the MINING AND SCIENTIFIC PRESS quotes \$16.50 per unit for impure concentrate and \$18 for pure ores. This is a difference of \$90 per ton of 60% concentrate. The cost of treatment by the method described is considerably less than this figure, and the product will bring a proportionately higher figure. The method practically follows one method of analysis for tungsten ore so that the extraction is practically complete.

Revival of Mining at Marysville, Montana

By L. S. ROPES

After a long period of practical stagnation, Marysville has assumed an activity that seems to assure an indefinite future of prosperity through the re-opening of a number of the old mines and the development of prospects long awaiting the touch of capital. With a record

third, the proving of the old and long-known Shannon prospect. These, with the advent of the Barnes-King Development Co., upon its purchase of the Piegan-Gloster group, and the later acquisition of the Shannon mine, for the proving of which the company paid a

SECTION THROUGH DRUMLUMMON MINE, MARYSVILLE

of \$50,000,000 produced in the past, and no failures among the earlier operators, it is surprising that the camp has been idle so long. Potent factors in the re-opening of the camp are, first, the reversion of capital to prospects and to old mines; second, the entrance into Deer Lodge of the power-lines from Great Falls, with power for a district that had been depleted of its supply of fuel through the earlier period of prosperity; and,

premium of \$200,000 over the purchase price, have attracted the attention of investors. The Gloster and Shannon are now in active production, and a mill of approximately 150 tons daily capacity is turning out from \$50,000 to \$75,000 per month. The St. Louis Mining & Milling Co. has been re-opening the Drumlummon mine, the mill being completed, with an installation of motors for electric drive, and it is now commencing operations.

This mill is of 125 tons capacity per diem. During the year, the Marysville Gold Mining Co., organized originally on the strength of the Annie Dillon property, has taken over several groups of claims, including the Blue Bird, Hickey, Mt. Pleasant, and Honey Comb mines, each having a small production to its credit, and it has been developing these for several months. The results attained have justified the belief in its possibilities. The re-openeng of the Blue Bird, closed and inaccessible for 20 years, explodes the theory that a mine in such a state breeds only fairy tales and myths. Cross-cuts and other exploration have already revealed unsuspected orebodies. Similar work in the Honey Comb has brought to light a previously unknown vein, which promises to become more important than the original mine. The Barnes-King Development Co. has secured an option on the Boyer property, a recent discovery that has given good results, which suggests that all the veins and lodes of the district have not yet been disclosed.

Marysville has been essentially a free-milling district. Crushing with stamps, amalgamation, and vanner-concentration, was customary. The St. Louis mill will follow the latter practice, while the Gloster mill is obtaining satisfactory results by all-sliming and cyanide agitation direct, without supplementary amalgamation or concentration. Owing to valuable sulphides in some of the ores, direct cyanidation will not be permissible, but a high recovery will be possible by flotation and cyanidation. Ores of this kind lead to a consideration of the lead-copper-silver deposits with only nominal gold-content, which have been prospected for years. Some of these prospects date back to the original location of the gold mines, when it was hoped that shipping or free-milling gold ore might be found. Around the margin of the gold-bearing area are a number of promising developments on such ores.

The Marysville district is an area of metamorphosed slates with interbedded micro-diorite sheets surrounding and overlapping a central exposure of quartz monzonite. These are cut by dikes of diorite porphyry. The contact of hornstones and granite, the terms locally used for the principal formations, varies from a vertical to a horizontal position, as also do the bedding-planes of the hornstone. The geology of the region has been given in Professional Paper No. 57 by Joseph Barrell, and also in Bulletin 527 of the U. S. Geological Survey, prepared by Adolph Knopf. The veins of the Marysville district vary from a few inches of bonanza-ore to others several feet in width, and there are also shear and breccia-zones from a few feet to 30 and 40 ft. wide, occurring in the monzonite and in the hornstone. Though not contact-veins, they may (as seen in the Drumlummon mine) follow closely along the vertical contact, and within one or the other formation, or they may strike transversely to the contact, as is the case with the Empire North Star vein of the Drumlummon, and with the veins of the Belmont, Bald Mountain, Gloster, Annie Dillon, and Spokane contacts of flatter position, while another series, remote from the exposures of the monzonite, appear di-

rectly related to the diorite-porphyry dikes. The strike of the latter veins is at sharp angles with that of the dikes which they penetrate, in some cases crossing into the porphyry, or hornstone, without decrease of metal-content. The Bald Butte is one of this kind, yielding 50% of its gross yield of \$3,500,000 in dividends; others of the same class are the Penobscot and Bell Boy, on the same dike, the Shannon on the west dike of the Mt. Pleasant area, the Blue Bird and the Honey Comb on the Blue Bird dike, and the Mt. Pleasant and Emma Miller on the Mt. Pleasant dike. The last, which constitutes the East dike, follows the granite-contact for several hundred feet to the east. Either class appears to be a case of fissuring and shearing due to shrinkage, with subsequent mineralization, in the monzonite or the

DRUMLUMMON HILL, NEAR MARYSVILLE, MONTANA

diorite porphyry, as the case may be, the mineralization probably being related to the porphyry dikes, as similar dikes are observed to cut the monzonite. Veins within the monzonite yield mostly gold, while in others the silver at times runs into hundreds of ounces per ton. Manganese is a prominent feature in some of the veins. Where it occurs low assay-values will be found in the upper zones of the lodes. This was noticeable in the Shannon and the Blue Bird mines, lying along the same lode, and also in other mines of the district. To this is attributed the rich zones of gold ore in such mines. The influence of manganese on the secondary enrichment of gold veins, discussed by William H. Emmons in Bulletin 529 of the U. S. Geological Survey, brings out these characteristics of the Marysville area. The outcrop in these cases rarely assays over \$1 per ton in gold, and the average prospector, not comprehending the fact that veins are not as they were made at the beginning of the world, as a rule passed them by. This is not surprising when even some engineers of intelligence seem uninformed as to such occurrences, and fail to see the significance of manganese in a splendid, though shallow exposure, and discourage deeper development. These enrichments are common in the Marysville mines.

Theory of Ore Flotation

By H. P. CORLISS and C. L. PERKINS

*The physics and chemistry of ore flotation constitute the subject of extensive literature, but no one contribution presents an explanation of all the physico-chemical factors involved. These articles¹ include collectively considerable information of importance, but have failed to elucidate this very obscure problem.

In this paper is presented an explanation of the actual factors involved in ideal flotation and also of other practical observations incident to the art. The theory presented herein has been substantiated by actual experiment, but only a brief résumé of the experimental results is included.

The greatest success in the art has been obtained in processes in which a gas, usually air, is introduced into the pulp, either by chemical means from carbonate and acid (Potter-Delprat process), assisted by vacuum (Elmore process), by the use of agitation (Minerals Separation process), or by blowing it in through a porous blanket (Callow process), and with or without the use of oil. The explanation offered in this paper is for this type of process especially, although the simple flotation-principles involved in such processes as the Maquisten, the Wood, and the bulk-oil process, are included. In all these processes the material floated must not be wholly wet by the water or solution in the presence of this gas or the material surrounding this gas, for example, an oil-film on the bubble-surface. If the material is completely wet by the water, it will not float, which is the case of the ideal gangue, while the material floated must go to the interface water-air bubble or entirely into the phase other than water, that is, the oil on the air-bubble.

The relations of the forces acting to produce this result were first stated by Freundlich², and enlarged upon by Hoffman³ and Reinders.⁴ They were first stated for the behavior of a sol, which will be called disperse phase 3 in liquid 1, when shaken with an immiscible liquid 2. Let

$T_{1\ 3}$ = interfacial tension between phase 3 and liquid 1,

$T_{2\ 3}$ = interfacial tension between phase 3 and liquid 2,

$T_{1\ 2}$ = interfacial tension between the two liquids.

If $T_{2\ 3} > T_{1\ 3} + T_{1\ 2}$ the sol will remain unchanged:

If $T_{1\ 3} > T_{2\ 3} + T_{1\ 2}$ the disperse phase 3 will go entirely into liquid 2;

If $T_{1\ 2} > T_{2\ 3} + T_{1\ 3}$ the disperse phase will collect at the liquid-liquid interface and will, if possible, separate the two liquids from each other.

If, however, no one interfacial tension is greater than the sum of the other two, then the disperse-phase will collect at the liquid-liquid interface, but the three phases will meet at a certain contact angle. The application of these principles to flotation may now be stated, for while the greater part of the material floated is much less disperse than that which is considered colloidal, the interfacial tendencies are the same, it simply being a question whether the forces holding the mineral to the interface are sufficient to overcome gravity, if the particle is to float.

Methods of flotation without resort to the use of oil are exemplified in the well-known Potter-Delprat process, in which CO_2 is generated in the acid pulp, but may be carried out successfully on some ores in a Callow cell, using air. Here, if flotation is to result, the mineral must go to the interface water-gas and be carried at this interface to the top of the pulp. The word water will be used mostly to denote the aqueous phase, whether it is pure water or a solution, and the floatable material will be called sulphide, since this is the common case. On the basis of interfacial tensions, where if

$T_{s\ a}$ = interfacial tension sulphide-air (or CO_2),

$T_{s\ w}$ = interfacial tension sulphide-water,

$T_{w\ a}$ = surface-tension water-air (or CO_2),

either (1) $T_{s\ w} > T_{s\ a} + T_{w\ a}$ or (2) no one interfacial tension is greater than the sum of the other two, must be true. It is obviously impossible to have $T_{w\ a} > T_{s\ a} + T_{s\ w}$ as the latter two are very large in comparison with the first, according to theoretical reasoning and measurements.⁵ Case 2 is the actual one, as can be seen if a drop of water is placed on a flat sulphide surface. Here the water does not spread over the entire surface, but comes to equilibrium with the three phases, sulphide, air, and water in contact at a certain angle. Case 1 would require that the water should not wet the sulphide at all in the presence of air. In flotation then the sulphide comes to the air-water interface and sticks through the bubble-surface to a certain extent, or is held in such a way that the three phases are in contact. The gangue material is completely wet by water and does not float, that is, $T_{g\ w} > T_{g\ a} + T_{w\ a}$.

Some measurements were made to get an idea of these

interfacial tendencies, by a method explained in connection with Fig. 1. Here a flat-ground mineral-surface was placed vertically in water or other solution as shown. By raising and lowering the mineral, a quite constant result was obtained for the rise of the meniscus against the mineral above the general level. Here the meniscus was always upward, showing a greater preference of the mineral for water than for air. In the case of the sulphides, when they were raised, the meniscus would soon draw back to a definite height, leaving the sulphide surface above quite dry. For gangue the water does not draw back quickly, but remains, wetting it for some time. The sulphides are proved interfacial in this way, and the measurements of the height of the point of contact above the general level are interesting. The measurements were made with a cathetometer.

Material	Water, mm.	0.1% H ₂ SO ₄ mm.	0.1% NaOH, mm.
Chalcocite	1.55	2.10	3.07
Chalcopyrite	2.60	2.50	2.90
Gangue (silicate)	3.20	3.25	3.30

The figures for the gangue are not at the point of contact, for there is none, since it is thoroughly wet by water, but are at the point where the meniscus becomes parallel to the face of the mineral surface. The mineral giving the smallest rise should be the most interfacial and the best floating. This was found to be true, for, without oil, chalcocite is a better floating mineral than chalcopyrite, at least for the ores that were tested. The figures above also show that in alkaline solution a very poor float should be made, as the rise is almost as much as for the gangue. This was also found to be true. Differences even among sulphides are clearly shown, hence it is not surprising to find all gradations in floating-properties among ores. These measurements, made on large pieces of mineral, with ground and partly polished surfaces, may not correspond exactly to those for an ore-surface, though in the cases mentioned they were found to give results agreeing with practice.

Another point noticed in these measurements, which is an important one, is how quickly the water is displaced from a mineral-surface when brought in contact with air. If an air-bubble comes in contact with a sulphide particle immersed in water, it must partly displace the water from the sulphide rather quickly if it is to be floated in a pneumatic cell. This was tested for the same minerals, by noting the time taken for the solution to come back to the final point of contact, when the mineral was raised, with the following general results:

- (1) Water and acid solutions are removed more quickly in air from chalcocite than from chalcopyrite.
- (2) Little difference is noted between acid and neutral solutions.
- (3) Alkaline solutions are removed very slowly from all sources.
- (4) All solutions adhere strongly to gangue.

These facts also agree with the practical results mentioned above. The success of the Potter-Delprat process

may well be due to these facts, since the CO₂ is generated in contact with the sulphide, and time is given for the solution to be partly displaced by the gas or, in other words, for the sulphide to attain the interfacial condition and be floated. When a soluble frothing agent is used, without oil, the same principles apply, the frothing agent simply modifying the water to a certain extent.

The use of oil introduces several new factors which make the problem more complex, but the same principles apply. The sulphides can now be interfacial between water and air as discussed above, but, in addition, may be interfacial between water and oil, or even go into the oil-layer. This oil-layer is on the bubble-surface and the forces holding the sulphides to this surface, if it has an oil-film, are much greater than when no oil is used. This point will be proved a little further on. The oil-layer on the bubble-surface need be only of minimum thickness to act, in contact with water, the same as a layer of oil on water, as far as interfacial tendencies are concerned. Let

$T_{s\ w}$ = interfacial tension sulphide-water,

$T_{s\ o}$ = interfacial tension sulphide-oil,

$T_{o\ w}$ = interfacial tension oil-water.

Then, if (1) $T_{s\ w} > T_{s\ o} + T_{o\ w}$, the sulphide will go into the oil-layer completely; (2) no one interfacial tension is greater than the sum of the other two, the sulphide will go to the oil-water interface, and the three phases will be in contact at a certain contact-angle. The gangue is thoroughly wetted by water, that is, $T_{g\ o} > T_{g\ w} + T_{o\ w}$.

These inequalities have been stated and applied to the flotation process by Ralston.⁶ The second condition given above, where the sulphides are interfacial, seems to be by far the most general, though the first condition may be, and probably is, realized, especially when tarry oils are used, which, in grinding with the ore, coat the sulphides more or less with this tarry material. It is doubtful if the lighter oils or the lighter constituents of a tarry-oil mixture film the sulphide at all in grinding, but rather it is probable that this oil is emulsified in the operation. The condition where the mineral is completely filmed by oil would be the best floating condition, and this could be realized in the flotation cell, where this film would be continuous with the oil-film on the bubble-surface. All gradations of the interfacial conditions are possible, from those that show only a slight tendency to be wet by water in the presence of oil, to those that are thoroughly wet, which is the case of the gangue-material.

Experimental determinations of the interfacial tendencies of various minerals were carried out in the same way as described above, except that in this case the interface was oil-water, or aqueous solution. In Fig. 2 is represented the case of a sulphide surface at this interface. The floatable materials were all interfacial, and the sulphides showed a decided preference for the oil. This is an important point in showing that the same

⁶M. & S. P., Oct. 23, 1915.

sulphides are much more strongly held to an oil-covered air-bubble than to one not so covered. In Fig. 1 the sulphide, while interfacial, shows a preference for water over air, and would easily be displaced in actual flotation from the interface and go back into the water. In Fig. 2

Fig. 1.

Fig. 2.

the meniscus is now pushed downward into the water, instead of upward, hence the sulphide is held much more strongly to oil than to air.

The following measurements were made after the meniscus had come to the true point of contact of the three phases, and this point was closely the same, whether the mineral was first wet with the oil or solution. The averages of these two figures are given. Kerosene, and a kerosene pine-oil mixture, were used mostly, as the interfaces are better defined, especially in acid and alkaline solution, than with many actual flotation oils. These other oils act in the same way, however.

DEPRESSION OF MENISCUS: KEROSENE AND CHALCOPHYRITE			
Water	0.1% H ₂ SO ₄	1% H ₂ SO ₄	10% H ₂ SO ₄
2.99 mm.	2.02 mm.	1.32 mm.	0.75 mm.

Calcite in contact with neutral, acid, and alkaline solutions and kerosene showed interfacial tendencies in alkaline solution only. Malachite exhibited a small interfacial tendency, except in alkaline solution in which it was thoroughly wet by the solution.

KEROSENE AND PINE-OIL AND AQUEOUS SOLUTION

This was a flotation mixture of 90% kerosene and 10% pine-oil.

Solution	Depression of meniscus	
	Chalcopyrite, mm.	Chalcocite, mm.
Water	3.10	3.42
0.1% NaOH	1.98	2.54
0.1% H ₂ SO ₄	1.45	2.95

Gangue-material in all cases is thoroughly wet by the solution, especially if it is wet by the solution before coming in contact with the oil, as is the case in actual flotation. The case of chalcocite in water, given above, is almost a condition of complete wetting by oil. These experimental results in every way justify the theoretical discussion given, and also show that alkali and acid lower the interfacial tension sulphide-water as the preference for oil is not as great in these solutions as in water, although the sulphide is still distinctly interfacial and hence can be easily floated from acid or alkaline pulps. These results were obtained by the use of a clean sulphide-surface, but in actual flotation this may not be

true for all the particles, and since the interfacial properties are a function of the surface only, one may expect many differences from these ideal measurements. In alkaline solution, for example, there may be some of the mineral which, like calcite, is more interfacial in this solution than in water, and hence would float, although it would not do so in a neutral pulp. In tests it has been found with some ores and oil-mixtures that in an alkaline pulp a better recovery was made in the usual length of time than by prolonged flotation in neutral pulp. This might be true also in an acid pulp for some minerals.

It has been noticed that some surfaces have a strong tendency to hold fast to the liquid, first wetting them and not to allow it to be easily displaced by another liquid. In the work upon interfacial tension, described above, such a surface would show a great difference in preferential action or angle of contact, dependent upon whether it was wet with oil or water first. It has also been observed that it is principally those substances having smooth or shiny surfaces which float, while those having dull or rough surfaces do not float. These observations and others point to the following explanation of the mechanism of this action: there is first the inherent property of each substance to adhere to oil or to water to a certain degree. When the substance is brought to the interface between water and oil, these forces tend to come to equilibrium with the third force, the interfacial tension between oil and water at some definite contact-angle. Here is where the physical nature of the solid surface comes into play. If the surface is smooth and shiny, such as that of a polished metal or a freshly fractured sulphide crystal, then the liquid first touching it is easily pushed back to the position of equilibrium. If, however, the substance has a dull, that is, a capillary surface, so that the liquid first wetting it is strongly held in its pores, then, when it is brought to the interface it may exhibit no interfacial properties at all, although, if it were smooth, it might even show a preference for the other liquid. This shows the reason for the difference, or hysteresis, of the contact-angle noted for some surfaces. It also explains why a particle having such a surface, if first wet with water, as is the case in flotation, will be very difficult to float, since it will not easily be brought into contact with oil.

The function of the bubble is to give a large surface to which the sulphide may go and be floated. As already stated, the air-bubble in oil-flotation is covered wholly or in part by an oil-film. For the action of oil on water, see Devaux⁷ and Langmuir.⁸ It is not necessary that the oil completely cover the bubble, and it probably does not in the greater proportion of the bubbles. The supply of oil for the bubbles will be discussed under the action of emulsions. If an oil droplet be placed on water or aqueous solution, it will spread over the surface provided the surface-tension of the water is greater than the sum of the surface-tension of the oil plus the interfacial tension oil-water, that is, this inequality must be true:

⁷Ann. Report Smithsonian Inst., 1913, 261.

⁸Met. & Chem. Eng., 15 (1916), 469.

$$T_{wa} > T_{oa} + T_{ow}$$

For oil-flotation this must be true for all solutions used, as the air in the bubble, surrounded by the pulp, presents this same condition. If to water be added some material which lowers its surface-tension (T_{wa}), without lowering $T_{wa} + T_{oa}$ to an equal amount, the inequality is reduced, and finally a point is reached where the oil will not spread on the solution. This is easily realized in the case of soap-solutions, and with many other substances that lower the surface-tension greatly. In this condition a poor float would result. In flotation, in order to produce a froth, material such as the soluble portion of pine-oil is added which lowers the surface-tension of water. Unless this helps in other ways than in producing a froth, it should be used in as small a quantity as possible, and this agrees with many practical observations. The frothing agent added also lowers the interfacial tension oil-water, but here it must be remembered that even if the interfacial tension be lowered in the same proportion as the surface-tension, the inequality is less than before, since the interfacial tension is much smaller than the surface-tension of water. The other factor, the surface-tension of oil (T_{oa}), is not changed much, for inorganic salts do not dissolve in it. If, however, some substance be added which will not lower the surface-tension of water but will lower the interfacial tension oil-water, then this should produce better oiling of the bubble. This can be done with alkalies and in the case of some oils by acids.

An important point in connection with the use of the pneumatic cell is the time during which the bubble is in contact with the pulp as it passes through, as here it must be attached to the sulphide particles. Any reagent that will give a quicker filming of the bubble-surface by oil, after it comes through the blanket, will be of benefit in the rapidity with which the mineral is attached and raised. Alkalies, as explained, produce a greater inequality between T_{wa} and $T_{wo} + T_{oa}$, and hence the oil will be spread out quicker over the surface than without their use. A large number of surface and interfacial tension measurements were made, a few of which are as follows:

SURFACE TENSIONS

	Dynes per cm.
Water 25°C.	71.8
Kerosene	25.2
Coke-oven oil	28.0
Pine oil	30.0
0.01% solution terpeneol	68.6
0.1% solution terpeneol	49.2

INTERFACIAL TENSIONS

Kerosene-water	32.8

Coke-oven oil-0.01% solution saponine.....	9.3
Coke-oven oil-0.01% solution tannic acid.....	12.7
Coke-oven oil-0.01% solution hemoglobin.....	8.9

Considerable data of this kind are given by Lewis⁹ and Shorter and Ellingsworth¹⁰ on the action of dyes, salts, and soap. The drop number apparatus used was the same as described by Shorter and Ellingsworth. Their work also shows that soap and alkali together are extremely active in lowering the interfacial tension oil-water. This would be the condition in an alkaline pulp, as there would then be free alkali and some saponified material with many of the oils used.

The results when colloidal material is present are subject to great variation, due to different speed of formation of drops. The figures given above for these materials approach the dynamic value, as the rate of dropping was fairly rapid. The static values are much smaller, and are interesting in connection with the emulsifying power of these substances. As an example of this the following result on coke-oven oil against 0.005% hemoglobin solution is given. The time is for the total number of drops formed.

Time	Drop No.	Interfacial tension, dynes per cm.
2 min. 40 sec.....	22.5	13.2
1 hr. 4 min.....	84.0	3.5

It is seen from the table above, that besides NaOH itself, any salt that hydrolyzes to give an alkaline solution lowers the interfacial tension, and all these salts are beneficial to flotation.

The behavior of the oil at the bubble and sulphide surfaces has been given. In the pneumatic cell this oil is supplied by an emulsion or a coarser suspension of oil in water. In the agitator-type machine, the oil may be beaten in at the cell, though it is also customary to grind the oil with the ore. In either case the problem of emulsions comes in. In the pneumatic process this emulsion is formed in the grinding and must be good enough to last throughout the float, yet not so good as to fail to break down with sufficient rapidity to give free oil for the bubble-surface. The subdivision of the oil is such that no doubt almost all degrees of dispersion exist; the larger droplets may be of sufficient size for one to coat a fair area of a bubble-surface, but the better emulsified portion is of such size that many particles have to unite to give oil enough for the minimum thickness of an oil-film, to spread over even a square centimetre. This can be calculated from the minimum thickness of an oil film¹¹ and the size of the particles in an ordinary oil-emulsion.¹²

Experimental evidence on these points is conclusive. If a coarse suspension of oil be made simply by shaking

⁹Zeit. phys. Chem., 74 (1910), 619.

¹⁰Proc. Roy. Soc., 92 (1916), 231.

¹¹Devaux, Loc. cit.

¹²Ellis, Zeit. phys. Chem., 80 (1912), 597.

the ore, oil, and water together in a bottle by hand, and then put in a small Callow cell, only a partial float results, and the operation must be repeated several times, adding more oil each time, in order to get a good recovery. If, however, too good an emulsion is had, a poor recovery results. For this purpose a kerosene pine-oil mixture was emulsified with water in a De Laval emulser and allowed to stand over night, and a middle portion of this emulsion was removed for the tests. This emulsion added at the cell gave a small float at first and then stopped. On adding a little acid no further float resulted, but, by allowing the pulp to stand for a few minutes, an additional amount of sulphide was raised, and finally a good recovery was made, though considerable time had to be given for the emulsion to give up its

emulsion than in the Callow process, and the value of acids and salts of this type consists in their power of breaking down an emulsion, or preventing too good a one being formed. These salts should be used in acid solution, or, otherwise, due to hydrolysis, the insoluble hydroxides formed, for example, $\text{Fe}(\text{OH})_3$, and $\text{Al}(\text{OH})_3$ have the opposite effect, namely, of preventing the breaking down of the emulsion or promoting its formation.¹³ Oil-emulsions in FeCl_3 solution, on standing, give a yellow flocculent precipitate, but the emulsion is not broken. The mechanism of this is discussed by Ellis.¹⁴ In a neutral, pneumatic, Callow float, such salts have been found to be harmful. If salts of iron or aluminum are present in the feed-water then acid may be necessary to prevent this action between them and the oil-emulsions.

TYPICAL FROTH FORMED IN A CALLOW CELL.

oil. This was also found to be true for another oil that gave an excellent emulsion on simply adding it to water.

It is interesting to note that in these cases it was proved that it was not necessary to grind the oil with the ore, but, by adding it as an emulsion prepared by itself, as good a recovery results. This probably is not true for oils containing tarry matter as explained above. It was also noticed in using the second emulsion, named above, that flocculation of the slime took place in neutral solution, and that these then floated to a large extent, giving a non-preferential float; when, on the other hand, the emulsion was broken by acid and alum, a good preferential float resulted. It was found that this slime in neutral pulp had flocculated with the oil-emulsion so that, on standing, all the oil was carried down, though the emulsion was not appreciably broken.

The value of acid and salts having a polyvalent cation has been demonstrated in some cases, usually in connection with the Minerals Separation type process. In this process there is greater danger of getting too good an

The value of alkalis has been discussed as giving a better oiling of the bubble-surface. In connection with emulsions, however, a greater effect can be ascribed to the action of alkalis or salts which hydrolyze to give an alkaline reaction, and to those which have a polyvalent anion. If a neutral ore-pulp is shaken with a small quantity of an oil-emulsion it is found that the slime is coagulated with the emulsion and settles out, often leaving the liquid quite free from oil-emulsion. The emulsion is not broken, but simply carried down with the flocculated slime. If alkalis are used, or salts such as last mentioned, then the slime is deflocculated in the great majority of cases. It then settles more slowly, and when it has settled the emulsion is left free and still standing. This is important, for now the emulsion is free to function as it should, that is, to give oil to the bubble-surface. The ore-particles, both sulphide and gangue, are also free to show their own behavior toward

¹³Briggs and Schmidt, *Jour. Phys. Chem.*, 19 (1915), 478.

¹⁴*Zeit. phys. Chem.*, 89 (1914), 149.

the water and the oil. This deflocculation should, and does, result in a higher grade concentrate and a greater and quicker recovery, since now no sulphide-particles are coagulated with, or surrounded by, gangue-particles that prevent their flotation.

The use of lime has not been found to be as beneficial as that of NaOH. This is explained by the fact that this substance due to the predominating effect of the calcium ion, coagulates instead of deflocculating the slime, and hence part of the emulsion is removed and the individual particles are not free to float as they should. This coagulating action may be more noticeable in a Callow cell than in a cell of the Minerals Separation type, as in the latter the coagulated slime may be broken up considerably, but the tendency is the same in either case.

The principles involved when varying quantities of oil are used, is a question on which there is great difference of opinion. From theory there should be no difference whether a large or small amount of oil be used, provided the oil is properly emulsified. If a large amount, 2% or 3%, be used, and is not emulsified sufficiently, the excess may float and be of disadvantage in several ways. To test this point a float was made with an amount of oil equivalent to 2% of the weight of the ore, emulsified in a De Laval emulser, and added at the cell (Callow), and a float made. It behaved in every way the same as when 0.2% or less of oil was used, and the recovery was better, with as high a grade of concentrate. Of course, economy would settle the minimum amount of oil to use. This was repeated with other oils and ores. The extra amount of oil used gave a greater oiling of the bubble-surface, and in fact these floats were better than when alkali was used to make the smaller amount of oil more efficient.

In the light of the above work the question of flotation 'poisons' was taken up with the idea that any substance which will prevent the breaking down of an emulsion or coalescence of oil droplets, or which gives adsorption of colloidal particles at the oil-water interface, is harmful to flotation. In the first two cases the proper amount of oil will not be freed, and in the other case the oil-surface, if formed, would be covered by an adsorbed layer, so that no oil-surface would be presented for attachment of the mineral. Experimental work, by actual flotation, had shown what substances, including many dyes, were harmful. Solutions of these substances of 0.01% strength were shaken in test tubes, with about 2 c.c. of oil, for a few minutes, to the same extent and at the same time. The tubes were then placed upright and the amount of emulsification and the rapidity of coalescence of the oil droplets rising to the top noted, with the following results:

(1) Slight or no emulsification and rapid coalescence of droplets when using methylene blue, safranin and bismarck-brown. These dull dyes really act like salts, and are not colloidal, nor are they harmful to flotation. In fact, these dyes assist slightly in breaking an emulsion.

(2) Extremely slow coalescence of droplets, the finely divided oil layer lasting for several hours to days, when

using congo-red, bengozurin, azo-blue, saponine, tannic acid, waste sulphate liquor, hemoglobin, and eosin. These substances are all injurious to flotation. Most of these are negative colloids. Hemoglobin is highly colloidal, and positive, and its adsorption is probably enhanced because it is oppositely charged to the oil-emulsion. Several of this last class of substances, especially saponine, gave marked emulsification, even with the small amount of shaking received. Some of these substances also form quite stable and viscous skins at oil-surfaces. Another experiment consisted in dividing an oil-emulsion into two parts, to one of which tannic acid was added, and then frothing over equal volumes of each in a small cell. The one to which tannic acid had been added contained 3.5 times as much oil in the residue or tail-water as the other. This shows that the oil-emulsion had been kept from breaking down, and the oil being frothed over. Besides the substances given above, the injurious effect of insoluble hydroxides of the heavy metals has been explained under emulsions. Other inorganic colloids have been found to be injurious, for example, when floating with $K_4Fe(CN)_6$, the $Cu_2Fe(CN)_6$ formed from the oxidized and soluble copper hurts the float very noticeably. The experimental evidence proves that the action of these colloids is, without doubt, as stated, though they may also adsorb at the solid surfaces, and in that way cause a poorer result to be obtained. It is easily seen how the water used in flotation and the slime coming from certain ores, have a great effect in flotation. This has caused some to say that it is the gangue that determines the success of the process, and if the water-supply be included in this, they are to a certain extent correct.

The froths produced in flotation are useful as a mechanical means of removing the mineral brought up by the bubble. The formation of a froth, and its stability, are due principally to dissolved materials in the water which give to the solution a variable surface-tension. The static surface of a solution has a lower tension than a fresh surface, whether the substance added lowers or raises the surface-tension of the solvent. Since a large lowering may be caused by a small amount of solute and only a small rise may be obtained, the best frothing agents are those that lower the surface-tension. Pine-oil is used to a large extent for this purpose in practice, the soluble portion causing a considerable lowering of the surface-tension of water. In many articles that have appeared on the theory of flotation, it has been stated that oils lower the surface-tension of water. This is not very clearly stated, since, as ordinarily understood, oil is insoluble in water, and only soluble material can affect the surface-tension of water. Besides the soluble portion of pine-oil, a part of many other flotation oil-mixtures is soluble and gives a froth. Terpeneol, menthol, and many such substances are powerful frothing agents. The lasting qualities of a froth, as stated above, are due to its variable surface-tension, for if a bubble starts to thin out or to break at a certain point this fresh surface has a greater surface-tension than before, hence

is automatically strengthened at this point and resists rupture. In using alkalis it is observed that a more quickly breaking froth results in a pneumatic cell. This can be explained by the fact, as stated before, that a greater extent of bubble-surface is covered with oil, hence there is less surface which contains only the adsorbed frothing agent, and since oils themselves do not produce good froths, the froth breaks more quickly than when alkalis are not used; or, this observation may be used to support the view that the bubbles are better oiled in an alkaline pulp. A froth is also stabilized by the slime present in a pulp, or by other colloidal matter. Colloidal material dissolved in the oils will make an oil-froth more lasting. A mixture of oils, the same as an aqueous solution, gives a better froth than a pure oil.

Considerable weight has been placed by many upon the electrostatic forces that might be present in the flotation process. Some have even considered the attraction that holds the sulphide to the bubble-surface to be of this origin. Air bubbled through water has been found to carry ions,¹⁵ and from this, and the fact that most substances have a contact-difference of potential when in contact with water or solutions, an electrical theory has been built up, though in many cases serious errors have been made regarding the action of these forces. Measurements were made to determine these forces. The small metal Callow cell used was grounded, as this condition prevails in actual practice. The charge carried by the air issuing from the flotation pulp was discharged on a metal screen placed above the cell, and the effect measured by means of a Dolezalek electrometer. The readings in this case are measured in volts per minute. The charge upon the air from several pulps was measured and in no case did it exceed 0.011 v. per minute, and was usually only about half that value. The air was negative in neutral pulps, but slightly positive in one of the alkaline pulps. The charge on the froth was also measured, and this varied from zero to 0.011 v. as the maximum. This was sometimes positive, and under other conditions negative. In two good floating pulps the froth was at almost zero potential, though 0.002 v. could easily be determined. It seems, then, that these electrostatic effects are far too small to exert any important part in flotation, and cannot possibly be the force that holds the sulphide to the bubble. This, too, would require a dielectric film, such as oil, between the two oppositely charged bodies, the sulphide and the gaseous ions in the bubble; but since flotation results without the use of oil in many cases, and, without doubt, the bubble-surfaces are often not completely covered by oil even when oil is used, it seems that this theory cannot hold. The contact difference of potential of various minerals has been used in some theories. These were also measured by an electro-endosmose method as described by Perrin.¹⁶ To this apparatus a small calibrated tube was sealed at the top of the dia-

phragm side, so that when dilute electrolytes are used the gas generated can be forced over into this tube, after the experiment is over, and this correction applied to the amount of liquid apparently transferred through the powdered material. The distance between the electrodes was 12 cm. and the potential 110 v. The results obtained give the sign of the charge on the solid in contact with the water or solution, but quantitative results as to the actual potential differences are difficult to obtain in this way. However, some idea can be had by comparing the amount of liquid transferred for the minerals, to that transferred in the case of silica, whose potential difference against water has been found by cataphoresis measurements. This is found to be approximately -0.042 v. For quartz and ferric hydroxide, see Whitney and Blake.¹⁷ The results obtained are as follows:

Mineral	Liquid	Sign of solid	Liquid transferred, cu. mm. per min.
Silica	Water	Negative	30.7
Alumina	N/100 HCl	Positive	40.0
Chalcopyrite	Water	?	Approx. 0
Galena	Water	Negative	3.6
Sphalerite	Water	Negative	6.1
Molybdenite	Water	Negative	3.7
Malachite	Water	Positive	4.0
Malachite	N/500 HCl	Positive	17.8
Galena	F. W./500 FeCl ₃	Positive	44.3

Here the sulphides tested are seen to be slightly negative against water, or practically zero in the case of chalcopyrite. This agrees with our ideas concerning the contact-difference of potential of these substances and with cataphoresis experiments on colloidal sulphides, and the like. Malachite is positive, as would be expected from its basic character. The last result given in the table is probably due to the formation, by hydrolysis, of ferric hydroxide, and its adsorption on the surface of the mineral, so that the action is exactly the same as for ferric hydroxide itself. In this case again, no attraction can exist on the basis of electrical charges between sulphides and oil in emulsions, since they are of the same sign. The charges on oil in emulsions in dilute salt-solutions, etc., are given by Ellis,¹⁸ Powis,¹⁹ and others. This, however, would not determine the charges on a mineral and oil, if the two were in actual contact, as is necessary for flotation. The charges carried by the oil in emulsions are important probably in connection with positively charged colloids which act as poisons, and, of course, the coagulation of slime, and the breaking of an emulsion by electrolytes, is a function of the charge carried by them; but it is not possible to use these charges as an explanation of the primary principles involved in flotation.

The following is a summary of the conclusions arrived at as a result of the experiments made:

(1) For an ore particle to float, it must be interfacial between oil and water, or it must go completely into the oil-phase. If no oil be used, the particle must be inter-

¹⁵Lord Kelvin, McLean and Galt, Proc. Roy. Soc., 1894, 57; Coehn and Mozer, Ann. Physik, 43 (1914), 1048.

¹⁶Jour. chem. phys., 2 (1904), 601

¹⁷Jour. Am. Chem. Soc., 26 (1904), 1339.

¹⁸Zeit. phys. Chem., 78 (1911), 325.

¹⁹Ibid., 89 (1914), 91.

facial between water and air. The force holding the particle to the bubble is much greater when oil is used.

(2) In addition to its value as a lifting agent, the bubble serves to produce a large air-surface in contact with the pulp. This surface is covered to a greater or less extent by an oil-film, to which the mineral may go, so that a small amount of oil is very efficient.

(3) The oil should not be so well emulsified that it will not be given up to the bubble-surface; and yet should be sufficiently emulsified, in a pneumatic process, to last during the time of floating.

(4) Colloids in general are harmful, owing either to their causing too stable an emulsion, or to their adsorption on the oil-film at the bubble-surface, preventing mineral attachment. This is the action of the so-called 'flotation poisons.'

(5) The froth formed is attributable either to the soluble portion of the flotation mixture, which produces a variable surface-tension, or to finely divided or colloidal materials.

(6) Acids, alkalies, and salts affect all these factors.

(7) The electrical effects, other than the colloidal charges, are not important in flotation.

(8) The nature of the solid-surface, in relation to its wetting properties, has been discussed and an explanation of the 'hysteresis' of the contact-angle advanced.

In the light of present knowledge it is impossible to measure many of the forces operative in flotation, such, for example, as the interfacial tensions between solids and liquids, or to explain the mechanism of adhesion. Such problems are, however, nearer solution, due to the material advances made recently by Laue²⁰, and by Bragg and Bragg,²¹ by which the actual arrangement of the atoms in a crystal may be determined, and also by Langmuir,²² whose work on the constitution of solids and liquids, the structure of solid-surfaces, and the mechanism of adsorption, leads toward the solution of this problem. While the flotation of each ore still remains more or less of a problem in itself, yet a clear understanding, and the proper application, of the principles involved will lead to an earlier solution of the problem.

COPIAPITE is a mineral of sulphur-yellow color, often with a shiny lustre, and superficially suggesting gold when occurring in masses. It is a basic sulphate of iron, $2\text{Fe}_2\text{O}_3 \cdot 5\text{SO}_3 \cdot 18\text{H}_2\text{O}$. It is a product of oxidation of pyrite under special conditions that are most often found in desert climates. It is seen at times accompanying copper ores where copper and iron vitriols are simultaneously formed; it is frequently formed in pegmatitic quartz dikes that had contained sulphides; it is also produced in the alteration of wolframite from the oxidation of the pyrite that is generally present in microscopic particles disseminated through the crystals; and it often occurs in thin films through rhyolite dikes from the oxidation of minute quantities of pyrite in the rock.

Perseverance Mine Powder-Thawer

By D. J. ARGALL

The powder-house of the Perseverance mine, near Juneau, Alaska, is situated 500 ft. north from the collar of the shaft, or 5-level station, at an elevation of 2300 ft. It is connected with the 5-level station by a covered tramway, or snow-shed. In the snow-shed, 42 feet from the powder-house, is a cement archway 20 ft. long, with a steel door in the middle, to serve as a fire-break. The building is 40 ft. long, 15 ft. 3 in. wide, and is constructed of lumber. It is finished inside with tar-paper on the studding and $\frac{7}{8}$ -in. ship-lap; outside is double ship-lap with tar-paper between. The roof is made of double ship-lap with maltoid covering. On this covering are 2 by 12-in. planks, and on top of these 2 ft. of loose earth. Earth is also banked around the sides and ends of the building, which is strongly constructed to carry an excessive snow-load. Last winter there were 10 to 15 ft. of snow on the roof. The extra heavy construction caused additional cost. The inside is divided by a partition, making two separate compartments. A car-track extends through the middle of each compartment. There are two 16-lb. rails, 18 in. apart, extending from floor to ceiling, and spaced 7 ft. centres, braced with $\frac{1}{2}$ -in. angle-iron. The angle-irons also support four rows of shelving placed around the sides of each compartment. The shelves are spaced 13 in. apart and are 18 in. wide. Each shelf is constructed of three 2 by 4-in. removable boards. Each compartment has a capacity for 320 fifty-pound boxes of powder.

Ventilation is provided in each compartment by 8 air-shafts, 8 by 12 in., through the ceiling, connecting with 12 by 12-in. air-duets outside. In front of each air-shaft is a slide-gate to regulate ventilation. The powder comes into the mine weekly from Thane, in 8-ton lots, is hoisted through the shaft, and trammed to the powder-thawer, and the boxes are placed on the shelves. The powder is thawed in the boxes without any unnecessary handling. This makes the thawing cheaper and less dangerous. After the powder has been in the thawer 48 hr. it is ready to be distributed throughout the mine as required. The usual method is to use each compartment alternately.

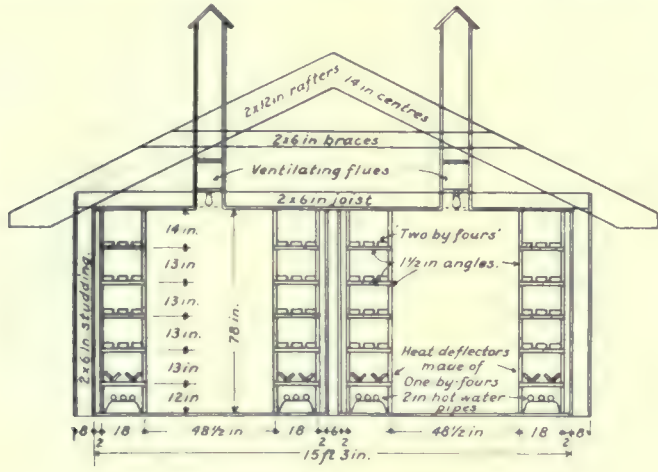

The hot-water heating arrangement is as follows: each compartment has 2115 cu. ft. of space, and is heated by two complete units consisting of a coil, and two 110-v. 4800-watt Bayonet heaters, with one thermostat in each compartment. The coils are placed 4 in. above the floor, under the shelving with heat deflectors. The Bayonet heaters are installed in a concrete station 5 ft. 6 in. wide, 8 ft. 6 in. long, and 9 ft. high, with a steel door, 22 ft. distant from the thawer. There also are installed the automatic controller, expansion tank, four 3-point heat-controlling switches, and a main line switch. One coil in each compartment is in constant operation. This coil is used to govern the heat, and is connected with the thermostat in the compartment. Each Bayonet heater has three points of regulation, namely, low, medium, and

²⁰Sitz. Akad. Wiss., Wien, June 1912.

²¹Proc. Camb. Phil. Soc., 17 (1912), 43; and treatise on 'X-Rays and Crystal Structure.'

²²Jour. Am. Chem. Soc., 38 (1916), 2221.

high. These heat-regulations are controlled by the four 3-way switches. By throwing in all the heat at one time a maximum temperature of 118° F. can be obtained, thus affording ample protection in case of extremely cold weather. It is, of course, understood that this temperature can be obtained only by throwing out the heat-con-

VERTICAL TRANSVERSE SECTION OF POWDER-THAWER

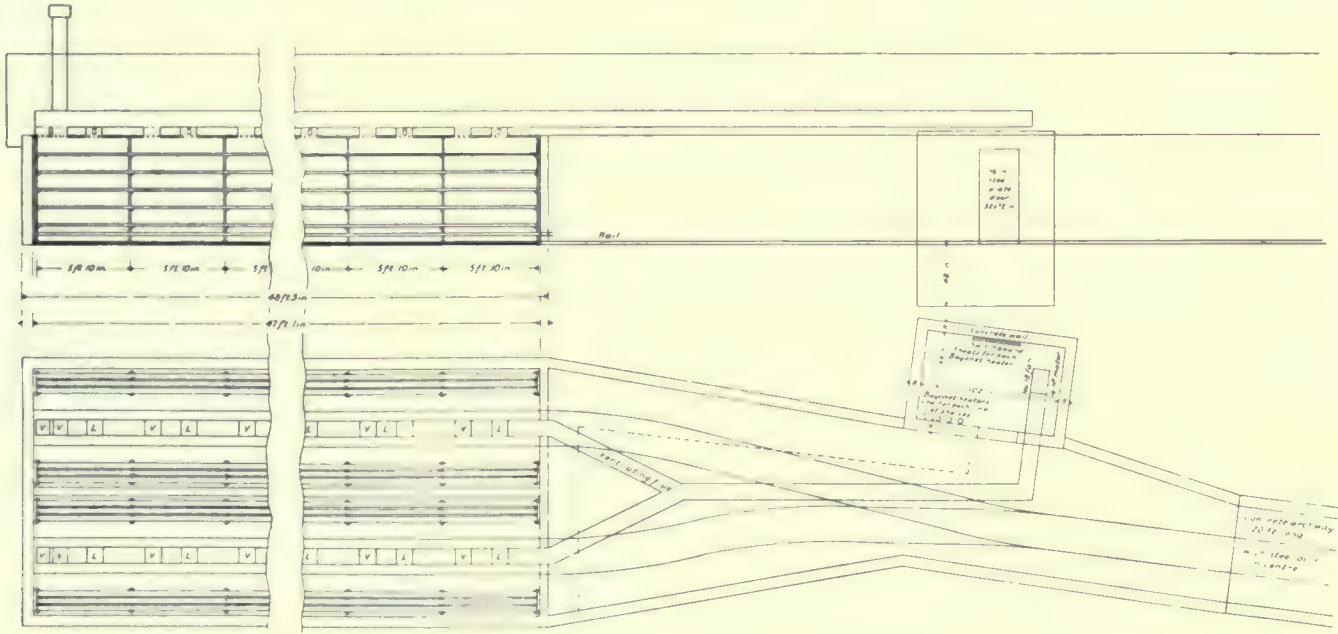

trolling device, as the thermostats are set to allow only a maximum of 90° F. Under ordinary conditions, setting the 3-way switches at the low position, has been found to take care of the requirements. The heat-controlling device consists of an aluminum expansion-band connected to a brass strip, at the end of which are platinum con-

The hot-water piping is arranged in four sections with 36 gal. of water in each section. There are 200 ft. of 2-in. pipe in each section. The air circulation in the thawer is accelerated by a 1 1/4-hp. motor, 110-v., direct connected to a suction fan, which pulls air from a 7 1/2-kw., 110-v. electric heating device, intermittent duty, and discharges uniformly to the thawer compartments.

Further details of the construction and its equipment appear in the table below:

Shelf capacity, tons	16
Number of compartments	2
Cubic feet per compartment	2295
Watts per compartment	625
Watts per cubic foot	0.273
110-volt Bayonet heaters per compartment	2
Size of Bayonet heaters, watts each	4800
Number of coils per compartment	2
Two-inch pipe per coil, square feet	200
Radiating surface per coil, square feet	184
Amount of water per coil, gallons	36.8
Watts required per gallon of water	8.76
Capacity of expansion-tank, gallons	5

All wiring for lighting is enclosed in a double galvanized-iron conduit. All outlet fittings are of the latest water and fire-proof marine type, making an ideal fire-proof installation. The powder-thawer is easily accessible from all parts of the mine. It is remote from other buildings, and the cost of heating is very low. When the current consumption was taken the outside temperature ranged from a maximum of 10° to a minimum of

PLAN OF POWDER-THAWER AT PERSEVERANCE MINE

tact-points which make a break-contact with a solenoid, which in turn is connected to the necessary levers which control the switch operating the Bayonet heater. The solenoid is wound for operating on a 110-v. alternating current. The expansion-tank has a capacity of 5 gal., which is more than ample, as the evaporation is practically negligible. A gauge-glass is installed on the tank for protection.

6° F. The inside temperature ranged from a maximum of 82° to a minimum of 76° F. The two 4800-w. Westinghouse Bayonet hot-water heaters required 30 kw.-hr. per 24 hours.

The construction costs were: labor \$2224.69; material and installation \$3588.22; total \$5812.91, representing a small capital expenditure for the capacity of the thawer.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

JUNEAU, ALASKA

THE READY BULLION MILL WORKING AT CAPACITY.—A NEW ENTERPRISE ON CHICHAGOFF ISLAND.—BIG GLORY HOLES BEING OPENED IN THE ALASKA JUNEAU MINE.

Since the flooding and the consequent shutting down of the Treadwell mines, things have been quiet on Douglas island. The Ready Bullion mine, the only one of the group still in operation, is keeping the Ready Bullion mill running to capacity. The cyanide plant is operating at present with one shift only, cleaning up the 240, 300, and 700 mills, as well as working the Ready Bullion concentrate.

All the machinery in the plants that have been shut-down is being salvaged and stored in warehouses until such time as it is needed, or is disposed of. No great change is apparent in the caved area, only small sloughs from the already shattered ground taking place continually. No word has as yet been given out officially as to the estimated value of the damage done by the caving and flooding of the mines.

Douglas City merchants have organized with a view to making up in some measure for the loss occasioned by the Treadwell shut-down, and to that end are making preparations to attract the business of the halibut fishermen.

Four sections of the Alaska Juneau mill have been placed in operation, this being one-third of the entire mill. No figures as to tonnage, or value of rock milled, are available as yet.

The inhabitants of Silver Bow basin are hearing the beat of machine-drills in the Alaska Juneau open-pits for the first time since the season of 1910. Four pits are being opened with a view to supplying the mill with an aggregate of 2000 tons per day.

The Hirst Chichagoff Mining Co. has taken a lease on the Hirst and Bahrt properties on Chichagoff island. The properties lie about 2000 ft. east of the Chichagoff mine, on the lode parallel to that of the latter. T. W. Shaffer, of Sitka, is superintendent of the property and expects to open up and equip the property to treat 50 tons per day by the end of this season. The company has a 15-year lease on the ground.

The \$20,000 gold brick recently stolen from the Chichagoff mine, has been found in the woods near the mine. Two suspects are awaiting trial in the Federal jail in Juneau.

MAYER, ARIZONA

EXTENSIVE DEVELOPMENT OF AN IMPORTANT OLD BUT NEGLECTED DISTRICT.—OLD MINES AND NEW ARE NUMEROUS.—NEW METALLURGICAL PLANTS AND A RAILROAD PROPOSED.

One of the least advertised, and yet one of the most promising mining districts of the State is in the vicinity of Mayer, in Yavapai county. It lies 16 miles south of the big mines at Jerome. The formation is similar to that at Jerome, the character of the ore is the same, and in one mine at least, a grade of copper ore is being developed which will rival the United Verde mine. Mayer is one of the old camps of Arizona. It is named after the late Joe Mayer, who settled on Big Bug creek in the early days of the Territory. The estate owns the Mayer townsite, which has become valuable due to the recent development of the surrounding mining district. It is understood that a deal is now pending with Eastern people for the

purchase of the townsite. The Mayer estate also owns several mining properties near the town, which is on the Prescott & Eastern railroad and in the centre of a rich mining region 20 miles square. A bank has recently been established here and a hospital is soon to be built.

There are from 20 to 25 producing mines in the Mayer district, each of which has a daily capacity of from 5 to 350 tons. The Blue Bell and the De Soto mines, owned and operated by the Consolidated Arizona Smelting Co., lead in the production. These are old properties that have been in course of development for some time. The Blue Bell outputs 350 tons per day, principally from the 800, 900, and 1000-ft. levels. The ore is chalcopryrite and pyrite which is broken from three separate ore-shoots ranging from 11 to 40 ft. wide. The shaft is to be sunk to 1100 and possibly to 1200 ft., at which levels drifts will be run to determine the extent of the orebodies.

The mine has over 5500 ft. of development and about 400,000 tons of ore developed. The De Soto mines is three miles south of the Blue Bell. It has 2000 ft. of development and an ore reserve of more than 100,000 tons. It is producing 150 tons per day. The ore from these two mines is shipped to the company's plants at Humboldt, where the high-grade is smelted and the low-grade treated by the flotation-process.

In a report to the company the general manager, G. M. Colvocoresses, stated that an increased saving of 20% has been obtained in the flotation-mill. The cost per ton is a little above \$1. The president of the company, Charles A. Kittle, states that in a little over two years the company has been able to pay off \$290,000 of floating indebtedness; has spent \$500,000 on improvements and extensions to the plant; has accumulated a working-capital of more than \$500,000; has changed a deficit of \$295,000 to a surplus of \$565,000; has paid \$44,250 interest on the company's outstanding bonds for the year 1916; has increased the ore reserves from 150,000 tons to over 600,000 tons, and has increased the production of copper from 500,000 to 1,750,000 lb. per month.

Next to the Consolidated Arizona in tonnage is the Big Ledge company which owns the Henrietta, Butternut, and Sterling mines, four miles north-west of Mayer. These are also old properties from which considerable ore has been shipped. The present owners have been pursuing a thorough system of development. The ore is sent to the Great Western smelter at Mayer, which is owned by a subsidiary company to the Big Ledge company. The smelter is being operated with one furnace of 150 tons capacity, which is being increased by the addition of a second smelter of 500 tons capacity. This will be ready to blow-in about July 1. The third smelting unit of 400 tons is already on the ground and will be set up as quickly as possible, which will bring the total capacity up to 1000 tons per day. The company is building a large power-plant at the rear of the smelter.

A company that has come to the front recently with several surprises is the Arizona-Binghamton Copper Co., which owns the Binghamton mine formerly owned by the Stoddard Mines Co. just north of Copper mountain. Practically all of the stock of this company is owned by W. H. Reynolds, of New York. A block of the stock was recently floated, largely in Arizona, at par. The mine is developed to the 600-ft. level with numerous drifts and cross-cuts, the most of which are in shipping-ore. The most recent work has developed high-grade ore. For a distance of 100 ft. a drift has been run on a 12-ft. vein that averages better than 20% copper. It is chalcopryrite with

streaks of copper-glance. This mine has had shipping ore from the grass-roots. The company has a flotation-mill at the mine with a capacity of 125 tons daily, which is being increased to 250 tons. The property earned a net profit of \$65,000 for the months of February and March, which was obtained principally from the lower grade ore that went through the flotation-mill. There is a joint agreement between this company and the Copper Queen company, which owns an adjoining mine, in the use of the mill. The Copper Queen company has the use of part of this mill without charge for one year. The Copper Queen company is controlled by people residing at Paris, Texas. It is a thoroughly developed property with sufficient ore reserves for a larger mill which is to be provided.

There is a long list of mines that are either producing a few tons daily or are making preparations to enter the shipping-list. Some of the best ones are: the Loma Prieta, Union, Bradshaw, Yaeger, Big Bug, Big Reef, Arizona National, War Eagle, Montezuma, United Arizona, Midnight Test, Wildflower, Little Jesse, Gold King, Iowa Copper, Hackberry, McCabe, Big Jim, Moscow, Minor, Stoddard, and Copper Mountain. These are scattered about within a radius of 12 miles of Mayer, and comprise only a small part of the producers of the district. It is known that at least six of the properties mentioned are being examined, with a view to purchase, by well-known engineers.

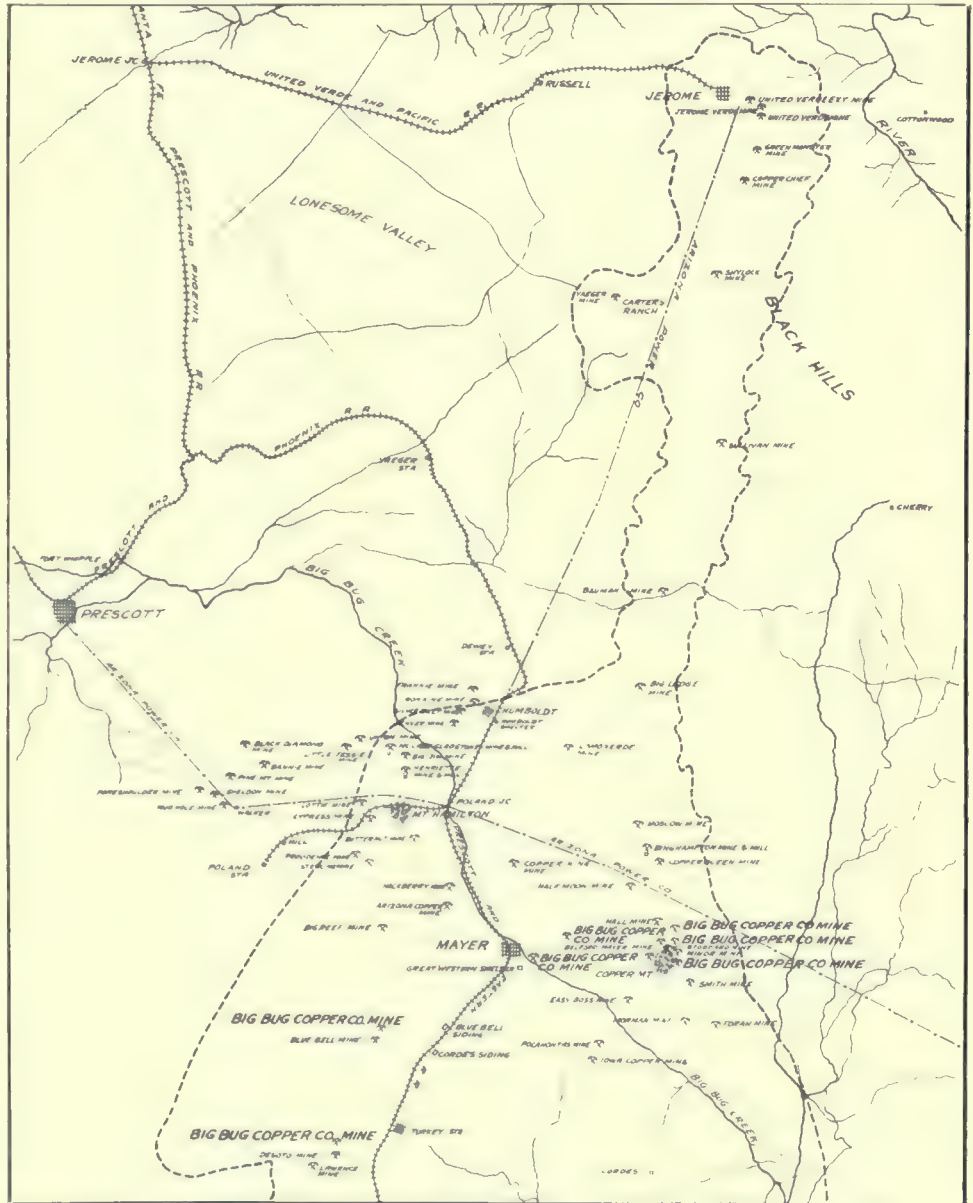

The Midnight Test mine is an old property, which, like many of the others, has been mismanaged and poorly developed underground. It is now owned by R. M. Merrill and Edward C. McManus, who are putting in their own money. Thus far about \$25,000 has been expended in cleaning out old workings, re-timbering the main shaft, and in new work. These men have found the lost orebodies, which were not worked out but lost by the former owners. One vein in particular has been driven on 280 ft. above the 400-ft. level, which has opened a surprise in high-grade ore. A 60-ton Nissen mill, built by former owners, is to be equipped with the flotation-process.

The Loma Prieta company has demonstrated what good mining methods will do in finding ore. This is another old and abused property. Under the new management, a shaft has been sunk 400 ft. with frequent drifts and cross-cuts showing ore in every new place. A small shipment of the ore was recently made to the testing-plant at Wickenburg with a showing of 8.6% copper and some gold.

The Union is another promising property in which recent work has developed something like 100,000 tons of ore that will average \$20 per ton in gold, silver, and lead. About 3000 tons of high-grade ore will run better than \$500 per ton.

Another very promising property is that of the Big Bug

Copper Co., which owns six separate properties, two adjoining the Blue Bell and De Soto, two near the smelter at Mayer, and two on Copper mountain, across the gulch from the Arizona-Binghamton. The company has commenced systematically to develop the several properties beginning on the Copper mountain mines. An excellent grade of copper ore outcrops in a net-work of veins on one of these claims, just as was found in the old Stoddard mine which is an adjoining property on Copper mountain. The Big Bug company has shipping-ore

COPPER REGION OF YAVAPAI COUNTY, ARIZONA, FROM JEROME SOUTHWARD

ready to break at this property, in old workings, that will run better than 15% copper. A rich surface-strike is reported that is 10 ft. wide and can be traced across the property 3000 ft. It is believed this company will develop a large producer at this Copper mountain camp with very little additional development work, for the ore is found at the surface with practically no overburden. On the company's property adjoining the Blue Bell mine, a shaft has been sunk 250 ft., which is nearly through the iron-cap, under which the Blue Bell orebodies lie.

The Big Reef company has found good shipping-ore in new work on a property two miles from Mayer. Extensive development work is being carried on which is making a good mine out of a poor old property.

It would be impossible to describe all of the mines and near-mines of this interesting district, for the reason that each day the work changes the previous day's report. Permanency of the orebodies has been established in several mines with workings from 600 to 1000 ft. deep. In the Blue Bell mine, for example, the main orebody is 40 ft. wide at the 1000-ft. level and shows double the width and value found when it was first opened. The ore of the district is amenable to the ordinary methods of treatment, smelting and flotation, as is shown at the Consolidated-Arizona smelter and flotation-mill. The shipping facilities of the district to company and custom-mills is excellent and climatic conditions are such that mining can be carried on every day in the year.

The building of a new railroad to Phoenix from Turkey siding, as contemplated by a newly organized company, would greatly benefit this district. It has already stimulated activity along the course of the survey, several properties having been bonded, and some sales actually made in anticipation of the railroad project going through. Such a railroad would serve a rich mining region. There is no question but that sufficient tonnage can be developed to supply the smelter, which is contemplated as part of the building plans. Mayer would be placed on a main line of railroad, and being far enough away from any other town of any size, would naturally become the principal place of business between Prescott and Phoenix.

MANHATTAN, NEVADA

IMPORTANT DEVELOPMENTS IN SEVERAL MINES.—THE WHITE CAPS MILL NEARING COMPLETION.—HIGH-GRADE ORE IN A NUMBER OF PROSPECTS.—FOSSILS IN THE PLACERS.

J. A. Cole, mine superintendent at the White Caps, reports that the shaft has reached a depth of 67 ft. below the fourth level. This represents an advance of 22 ft. for the week, good progress in sinking a double-compartment shaft. The flow of water in sinking is not over 2000 gal. in 24 hours. The sinking-pump, ready for use, so far has not been in operation, as the bailing takes little time and is less trouble to the crew than the large sinker. The ground through which the shaft is being sunk is a hard cherty material, but breaks well. The excessive flow of water in the east-drift work from the third level has not diminished. It was fortunate that the flow was struck in the middle of the shift, for if the water had not appeared until the round was shot, probably the entire lower workings would have been flooded and great damage done. The water was struck in a cut drill-hole and was plugged before the sump was filled. A 4-in. pipe with a pressure-valve has been put in. At present, there is 65 lb. pressure on the valve, in five minutes after shutting off the flow. The water is siphoned from the third to the fourth level, where it is picked up by the large station-pump, and by using the auxiliary station-pump intermittently, the water is kept under control, and none escapes into the shaft. The present flow handled by the pumps averages 200 gal. per minute. Similar flows of water have been encountered in running the drifts, just before striking the orebodies. A flood-gate is being installed in the west drift on the third level, as the management believes in preparedness. In the construction work in the White Caps mill, the roaster-shell has been completed. The form for the brickwork for the first hearth also has been finished. When complete the furnace will have seven roasting-hearths and one drying-hearth. The roaster is expected to handle approximately 125 tons for each 24 hours of White Caps ores. The maximum capacity is 175 tons, the difference in tonnage handled depending on the heat required in roasting the ore, a dead roast naturally requiring more time to each charge of ore. The mine ore-bin has been completed, and a Dodge crusher is installed close to the collar of the mine. The crusher building, 20 by 60 ft., is in process of erection. The main belt-conveyor is complete, and this finishes the installa-

tion of all the belt-conveyors with the exception of a short section to the roaster which soon will be finished. The new wagon-road to Pipe Springs from the White Caps has been completed to the first summit.

The shaft of the Morning Glory has reached a depth of 90 ft. The superintendent, Mr. Nelson, states that the formation in the bottom of the shaft is broken limestone. The value, which has shown for some distance in the shaft, is steadily increasing as depth is gained, and a vein carrying payable ore may be cut at any time. In addition to sinking, two shifts of miners are employed in prospect work from the bottom of the old Nelson Lease shaft. This shaft is 75 ft. deep and is between the company shaft and the White Caps west side-line. Considerable trenching has been done by the company along the breaks showing on the surface. To be able to carry on extensive work the management plans to make a change in the hoisting-equipment, replacing the 20-hp. hoist with a 40-hp. electric-hoist and motor. In addition, an air-line will be laid to the Consolidated mine-plant, when sufficient air will be available to operate two drills. Two jack-hammer drills have been ordered.

In the Manhattan Consolidated workings, on the 300-ft. level, 71 ft. east from the shaft, the fault, which has been defined both in the upper levels of the present working-shaft and in the workings from the old shaft, was struck and the face of the drift is now into the fault-zone 10 ft. It is impossible to state definitely its width, as the various places where cross-cut it has shown a width of from 10 to 40 ft. The orebody is known to be directly in contact with this in the old workings. On the 200-ft. level, the fault strikes north-south, and the orebody ends when the fault is reached. On the present 300-ft. level the fault recently cut strikes east-west, parallel with the vein. Due to the loose broken-up condition of the fault the progress is slow, as every foot of the cross-cut has to be heavily timbered. There is but little water thus far. The showings of sulphide-ore in the bottom of the west winze from the main workings of the Train Chase lease, on the Mustang claim, still appears strong as the winze is being sunk. Work has been concentrated in this winze, as the sulphide ore is considered as more permanent and the value of the ore is higher than when the ore-chimney was first developed. Samples taken from the bottom of the winze, a depth of 18 ft. since finding the high-grade sulphides, show \$600 per ton gold. The ore-chimney is close to the contact, although all sides are still in the limestone. The schist hanging wall is distant 8 ft. from the ore. As this rich ore is broken it is sacked and shipped to the smelter.

Recently some interesting fossils have been found in drifts in the deep-placer in the Searchlight claim, in the main Manhattan gulch, three miles west of the town. At a depth of from 70 to 80 ft. several large partly fossilized bones have been uncovered. One in particular, a portion of a shin-bone, was 15 in. wide and nearly 2 ft. long. This specimen was sent to the Smithsonian Institution. The latest specimen unearthed was a horn thought to be from a species of buffalo, not of large size but well preserved, and with curious deep indentations and ridges lengthwise of the horn.

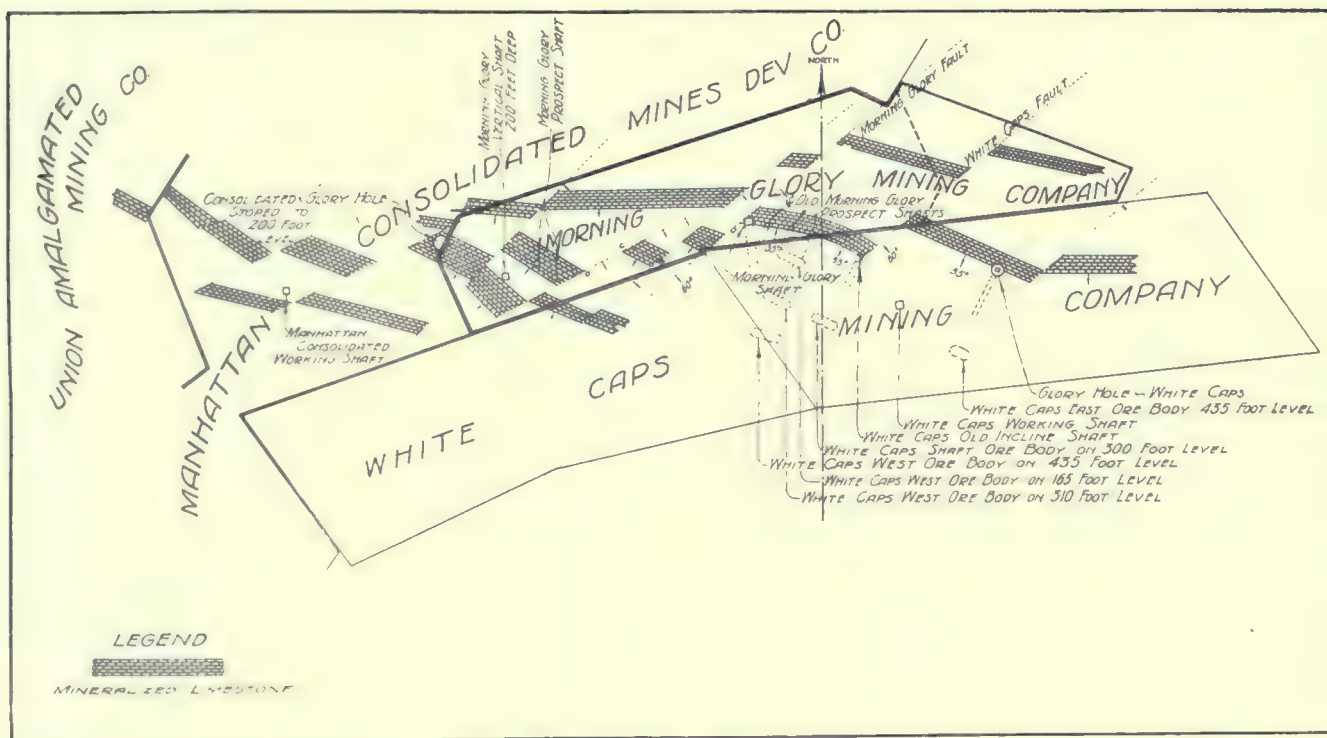

The shaft of the Red Top has reached a depth of 85 ft. In the bottom of the shaft there is a change of formation from the lime-shale into massive limestone, in which the vein-system that follows the limestone has been proved on both sides of the Red Top workings.

At the Union Amalgamated property, from the 600-ft. level, the east drift has advanced 32 ft., now a total of 210 ft. from the shaft. During the week there has been some machinery break-downs which has decreased the footage usually made. Work is being concentrated in the east drift with three shifts. The flow of water from the east drift has lessened and no further delays from that cause are anticipated. The company mill has been supplied with ore from development work and some tonnage has been mined from the west orebody, which

contains high-grade ore but is irregular. It has been necessary to employ ore-sorters, by which means a good milling-grade of ore has been obtained.

The east drift has been run on a fault-plane and has been in low-grade ore for several feet. This fault cuts the limestone bedding-planes diagonally. To cut the downward extension of the free-milling orebodies developed in the upper levels of the Earl claim it will be necessary to leave the fault-plane and take a more south-east course. These orebodies have yielded a large tonnage of good ore from the Earl workings. The Swanson lease, which first developed them, has a record of having yielded \$50,000. The ore averaged over \$25

per ton for this clay. He is making arrangements to handle a greater output than ever before. The Theo. Dittell Co. has met with some difficulty in securing the desired site for its factory, at Carbondale, but this doubtless will soon be adjusted, enabling the company to carry out its plans for the manufacture of chinaware from the kaolin mined on the Clark & Sons ranch and the Amick pits. In view of the valuable glass-sand, also mined on this ground, considerable interest is taken in the fact that Eastern parties have just bought a half interest in the Patterson Glass Works, at Stockton, for \$75,000. In the past six months the production of window-glass by that company has totaled about \$350,000, and it is

BLOCK-FAULTING AT MANHATTAN. THE ORE IS FOUND ALONG THE FAULT-PLANES IN MOST OF THE MINES

per ton in the mill. The width of the Swanson orebodies in many places was close to 25 ft. The milling of the ores extracted during development work is paying mine and mill expenses.

The cross-cut in the Amalgamated Extension property reached the lime-belt on May 20, and has since been advanced 7 ft., cross-cutting the bedding-planes of the limestone. Driving is now in progress, to get under the ore-shoot, which shows a strong outcrop. In a small break in the limestone in the face of the drift the ore gives good pannings of coarse gold. It is probable that this streak will lead to the main orebody, which is expected in about 26 ft. in advance of the present face. A second shift of miners has been added to the crew of the Extension, which should make the average advance of the drift about 7 ft. per day.

SUTTER CREEK, CALIFORNIA

EXPANSION OF THE CLAY INDUSTRY NEAR IONE.—MORE TAILING TROUBLE FOR THE DEEP GOLD MINES.—HIGH-GRADE ORE NEAR COPPERPOLIS.

Work on the clay deposits in the vicinity of Ione is progressing satisfactorily. A. B. Wallen is opening up a fine body of clay near the Dutschke place; tests show his shipments to be of standard quality and he has no difficulty in marketing his product. M. R. Bacon, superintendent for Clark & Sons, announces that he is nearly through stripping and will begin digging clay very soon; as there is a large de-

mand for this clay. He is making arrangements to handle a greater output than ever before. The supply of which is very large.

Protests against the filling of streams by means of sand from the mills in this county have been made in letters addressed to several of the mine owners by the Corps of Engineers of the United States. The impounding-dam of the Kennedy company became undermined, permitting some of the tailing to escape. A break in the Central Eureka tailing-dam also has caused trouble, but steps are being taken to remedy this difficulty. The Keystone and Original Amador Mining companies were permitted to resume operations upon giving bonds for the prompt repair of their impounding-dam on which work is now under way.

The extended delay in the receipt of some of the electrical equipment for the Old Eureka hoisting-plant has so far prevented putting the new hoist and head-frame into service, and the temporary hoisting-equipment continues in use. Everything is in readiness, however, including the installation of the new hoisting-cable, so that after the arrival of the delayed parts, no time need be lost. The machinery in question was ordered over a year ago. In the meantime, the work of cleaning out and repairing the levels continues steadily and sufficient pay-ore has been found in sight to assure the future prosperity of this old mine.

In Calaveras county the Royal Consolidated Mines, at Hodson, will shortly resume operations, as all indebtedness has been paid off. W. A. Bret, of Boston, the president of the company, has just spent a couple of weeks on the property.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

Many of the copper mines of the world also produce a large amount of silver, and a few of them produce some gold. The following shows the silver production of a number of so-called copper and zinc producers during the past two years (in ounces):

	1916	1915
Anaconda	11,837,769	9,005,617
Butte & Superior	3,669,950	3,385,164
Calumet & Arizona	1,863,149	1,381,077
East Butte	556,542	318,124
Greene	1,881,816	635,997
North Butte	1,047,063	940,631
United States Smelting	11,647,205	12,071,863
Utah Cons.	558,845	370,985
Utah Copper	461,596	371,712

ARIZONA

COCHISE COUNTY

(Special Correspondence.)—The increase of the present capitalization of \$3,500,000 to \$5,000,000, par value of shares \$10, will give the Denn Arizona the funds it needs to fully open the mine, which was closed in 1912 because of excessive overhead charges following the large increase in the inflow of water on the 1600-ft. level. The Junction, sinking to the 2000-ft. level has since shown that the water problem can be overcome through co-operation with the Calumet & Arizona. The Denn should be a large producer in 1918. The control of this property at present rests with the interests in control of Shattuck-Arizona. Calumet & Arizona, however, is understood to own a considerable block of the Denn shares. The new issue will be offered to present shareholders. Any part they may not subscribe for will go on the open market.

Bisbee, May 18.

MOHAVE COUNTY

(Special Correspondence.)—For the first four months of operation, the United Eastern mill treated 22,473 tons of ore having a gross value of \$504,615.47, being an average of \$22.35 per ton. Average extraction for the entire period was slightly under 96%, and working costs and losses averaged \$8.28 per ton. The total net profits totaled \$311,774.09.

The total number of tons milled per month for the period increased from 3800 in January, to 6706 in April, and May will exceed that amount. With the mill now in perfect running order it is expected that the daily average of 225 tons, established in April, will be maintained or perhaps exceeded.

F. O. Altinger, an assayer, has been arrested, charged by superintendent Burgess of the United Eastern with having received stolen high-grade ore from that mine, valued at several thousand dollars. He is alleged to have a complete milling and cyanidation-plant, in which the gold was extracted. The high-grade ore from the United Eastern runs from \$1 to \$5 per pound in gold, though the seam containing such value is narrow.

The new Tom Reed 300-ton Allis-Chalmers ball granulating-mill was started Saturday, May 26, and it demonstrated its efficiency by grinding nearly its full capacity from the start. Ore is being brought down from the Aztec shaft by auto-trucks pending the installation of the 4000-ft. tramway which is being erected.

The Gold Road mine is being rehabilitated, and the mill put in order. A vein of ore 4 ft. wide, 400 ft. long, and 400 ft. in vertical depth is being opened-up and blocked-out. In addition

to this orebody, the drift is being extended east on ore and a winze is being sunk from the 400-ft. level in ore assaying between \$15 and \$20 per ton. Experiments have been conducted with the flotation-process at the Needles smelter of the U. S. Smelting, Refining & Mining Co., but so far without proving that oil-flotation will work successfully and profitably with ore from the Oatman district, which is entirely free from sulphides and essentially a cyanidation ore.

A demand for higher wages on the part of the miners employed in the district has been rejected, but a counter proposition, offering a sliding-scale and an increase of about 25c. per day has been made by the operators.

Oatman, May 29.

CALIFORNIA

The State supervisor of oil and gas reports to the State Mining Bureau for the week ended May 26, 38 new wells started, making a total of 471 since the first of the year; 26 wells ready for test of water shut-off; 13 deepening or re-drilling, and four wells abandoned.

CALAVERAS COUNTY

(Special Correspondence.)—At the Mokelumne Hill group sinking continues, the shaft is down 350 ft., and the ore is improving with depth. The mill is running on ore from the west stopes.

Mokelumne Hill, May 28.

(Special Correspondence.)—P. B. R. Lightner, of Stockton, has re-opened the La Petite mine near Railroad Flat, and sinking is in progress, now down 100 ft., with good free-milling ore in sight.

Railroad Flat, May 28.

FRESNO COUNTY

(Special Correspondence.)—The Copper King mine under the new management, has made its first shipment of 25 tons of 10% ore to the Mammoth smelter, and shipments are to be continued regularly. C. D. Demarest, of the Angels Iron Works, is manager. The company is headed by B. N. Garrett, president of the Houston Bank and Trust Company, of Houston, Texas. The Copper King mine was operated from 1889 to 1893 and was equipped with a smelter, situated at Seal Bluff landing, on Suisun bay. Operations under the old company were disastrous, but under existing conditions and shipping to a custom-smelter the enterprise has entered on a career of prosperity. Ore is being developed in the mine, and a large tonnage is said to be available.

Fresno, May 31.

SHASTA COUNTY

(Special Correspondence.)—The Mammoth Copper Co. is devoting much attention to outside properties with gratifying results. Shaft-sinking at the Stowell is proceeding steadily with a view to opening the orebodies to considerable depth below the developed area. The Donkey mine, adjoining the Afterthought, near Ingot, has been equipped with an electric-hoist and the shaft is being deepened. The Friday Lowden is receiving attention, and considerable work is being done on claims adjoining the main Mammoth mine. Three furnaces of the Kennett smelter are kept in constant operation, and preliminary trials are being made with the new electrolytic zinc-plant.

The Arps Copper Co. has placed orders for a hoist, compressor, power-drills, and other equipment, and is preparing to

sink the shaft deeper and start comprehensive lateral development. The superintendent expects to increase the working force shortly, and satisfactory deep explorations will likely result in the installation of a flotation-equipment. The mine adjoins the Bully Hill group, near Winthrop, and contains high-grade copper ore, some of which is rich in silver.

The Bell Cow gold property, near Ono, has been taken under bond by C. L. Wilson and vigorous work started. The mine has been developed from a prospect into a promising property by T. P. Ames and Frank A. Greene, of Ono. Wilson developed the Arps copper mine from a prospect into a good producer, and also rehabilitated the old Texas group, near Whitehouse.

Dewatering of the Midas mine, at Harrison gulch, is proceeding steadily, and the management expects to start extensive development below the 1000-ft. level before summer ends. Some work is going forward in the Gold Hill mine and upper parts of the Midas. All mine equipment is now electrically operated and the numerous troubles caused by unsatisfactory steam-equipment has been eliminated.

Kennett, May 30.

TRINITY COUNTY

The Trinity Star Mining Co. is building a dredge to cost \$125,000. It will work on the Paulsen ranch near Lewiston.

TUOLUMNE COUNTY

(Special Correspondence.)—The Buchanan mine, on the high divide between the Main and South Forks of Tuolumne river and an early-day producer, is to be re-opened by the Buchanan Consolidated Mines Co., which has just been incorporated under the laws of Nevada. The authorized capital of the company is \$1,000,000, with shares at \$1 each. The incorporators are F. M. Carter and Fay Chadbourne, of Oakland; F. R. Vincent, of Alameda; L. E. Carter, of San Francisco, and C. W. Mitchell, of Pasadena. The amount to which the company may become indebted is limited to \$125,000. Besides having a good record to its credit, it took a spectacular place in local mining history years ago, when a large number of Chinese employed in the mine were marched out from the property by a body of armed men that had been organized in Sonora.

A new mill, the invention of O. A. Ellis, has been installed at the Chaparral mine, which adjoins the Buchanan on the south, and will make its initial run shortly. Crushing is done by iron balls weighing 450 lb. each, rolling on a concave circular track, the balls being propelled by a revolving grooved circular top. It is claimed the mill, which can be operated with 5 hp., will have a capacity of 25 tons daily.

An option on a tract of land near Rawhide, owned by John Madrid, has been given to Harry C. Warwick, of San Francisco. The property is said to contain valuable magnesite and chrome ores.

A vein of rich ore, 8 in. wide, has been uncovered in the Hand Over mine, near Arastraville, under lease and option to Messrs. Headrick, Wilson, and Gianelli.

It is expected that operations will be resumed at the Clho mine, at Jacksonville, early in June.

An outside company has taken a bond on the Italian Camp group of mines, 5 miles east of Columbia, and it is understood active operations will begin at once.

Sonora, May 28.

NEVADA

CLARK COUNTY

(Special Correspondence.)—This week an important strike was made in the Yellow Pine mine which is equivalent to the discovery of a new mine. It is on the 700-ft. level in a part of the mine heretofore never prospected and the lead and zinc content is somewhat higher than the average run-of-mine ore, being 18% lead and 35% zinc, and carrying approximately 30 oz. silver per ton. This amount of silver is unusual in the Yellow Pine ore. A cross-cut in this ore is now out 40 ft. and still in ore.

C. A. Overmire of the Pacific Platinum Works is conducting a series of large-scale tests on the copper-platinum-palladium ore in the old stopes and on the dumps at the Boss mine. This ore was mined before the rare metal content was known.

Until a tram can be installed at the Platino mine the copper ore is being packed down the hill by burros. Every four-footed long-ear in the district has been commandeered.

Of the new dry-concentrators, the Christmas Consolidated is of especial interest, due to the high-grade product it is turning out from a rebellious ore.

The Goodsprings Sampling Works, at Jean, on the Salt Lake road was inspected by J. M. Bidwell, general manager for the Garfield Smelting company, last week. A great advantage of this plant to the district is its facility for handling small shipments for lessees. Some of these receiving settlement for cars last week were Gallagher & Reid; Blackburn, Becraft & Smith; S. C. Root; and the Christmas Consolidated.

E. S. Armstrong, of Pasadena, California, who recently purchased the Hoosier mine, has discovered that the lead ore has an appreciable amount of lead molybdate. It is probable that considerable of this has been shipped with the regular lead shipments.

Moapa reports the discovery of oil. It occurs at a depth of 2000 ft. and, while not a large flow, is of excellent quality.

Goodsprings, May 28.

ESMERALDA COUNTY

(Special Correspondence.)—Stoping of shipping-ore has begun in the south drift on the 840-ft. level of the Kewanas, and A. I. D'Arcy, the manager, expects to start shipments in a few days. The south drift has been in ore for 100 ft., the vein ranging from 2 to 4 ft. wide. Shipping material is exposed in the north and south parts of the property, with approximately 1200 ft. of the main orebody yet to be explored between these points. The development of flotation-ore is also proceeding.

The Red Hill Florence Co. has re-timbered its 800-ft. shaft to the 500-ft. level and installed a 60-hp. electric-hoist. Arrangements are being made to drive north and south from the 500-ft. level to develop the orebody opened on the 200-ft. level by the north-west cross-cut. As soon as this work is completed cross-cuts will be run to find the Florence vein.

The Great Bend is producing a small tonnage of ore assaying \$26 to \$30 per ton in gold. The best ore is coming from stopes above the 160 and 300-ft. levels. Considerable milling-ore has been recently exposed and as soon as a sufficient tonnage is blocked out the small mill will be overhauled and placed in service.

The Sunset Mining & Development Co. is preparing to repair the 600-ft. shaft on its Denver claim, and to sink it 100 ft. deeper. Good ore is stated to be exposed at the 600-ft. point and extensive development will be done on this level. It is stated by the owners that large quantities of ore assaying \$10 to \$20 per ton are exposed in the old workings, and on the dumps. Sufficient water to operate the enlarged mill has been secured. The property is near Rhyolite.

The Mount Montgomery Mercury Co. has been organized by Goldfield men to work a group of cinnabar claims west of Belleville. Ore of excellent grade is said to be exposed. F. C. Beedle is president, and A. J. Bogard, Jr., secretary.

Goldfield, May 28.

NYE COUNTY

(Special Correspondence.)—The work of unwatering the old Tybo mine by the Louisiana Consolidated Mining Co. was started May 26. Two big Cameron pumps were put in operation, the power being furnished by the auxiliary steam-plant, as the 24° fuel-oil for the Diesel engine has not yet been delivered. The shaft is now 425 ft. deep and the water reaches the 300-ft. level. When the water is out, sinking to 800 ft. will begin and the development of the mine to that level will proceed. As shown by the report of John B. Farish, and others, the ore on the 400-ft. level is 64% richer than above and it is

believed that the vein will go to great depth. The vein accompanies a nearly vertical porphyry dike cutting horizontal limestone beds. The Louisiana company has a prospector in the field and he has found a likely looking prospect eight miles south of Tybo. The pay-streak is eight inches wide and the first sample went \$70 per ton in silver.

Tybo, May 29.

(Special Correspondence.)—What appears to be a phenomenal strike of gold ore has been made in the War Eagle group of mines in a range of high hills three miles east of the old camp of Goldyke. At Luning and Mina nearly every man has a specimen of the ore, some of them containing hundreds of dollars in visible gold. An option was given on the property for several thousand dollars, and the parties holding the option are said to have taken out more than the price agreed upon by merely prying and gadding off a few slabs of rock matted with gold in a shallow cut. A stampede is in progress and the entire country is being staked and re-staked. The prospects for personal encounters are considered quite as good as for high-grade ore, under the stimulus of the present excitement. The strike is described by an engineer who just came in from the district as being on a contact of lime and rhyolite. High-grade copper ore, mostly chalcopryite and glance, occurs on several claims. High-grade galena, some of it solid with silver, also occurs.

Luning, June 2.

The Tonopah Extension company reports the net earnings for April at \$34,248.46. The Tonopah Belmont bi-weekly clean-up, May 25, is reported as valued at \$144,780.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—A new strike has been made at a depth of 200 ft. in the Lynchburg mine under the control of the Empire Zinc Co. This is one of the Kelly mines that has not been operated for some time. The strike is a massive copper sulphide carrying from 15 to 20% copper.—Some Tulsa, Oklahoma, capitalists have formed a company to develop the Lone Tree group of mines, about three miles from Magdalena, and work has been commenced. New air-compressors and drills have been ordered and will arrive this week. This property gives promise of becoming one of the best producers in the vicinity. The Buckeye Copper Co. is doing a large amount of development at its properties near Water Canyon in the Magdalena-Kelly district. Over 20 men are employed in installing the new machinery. The new equipment includes a 100-hp. Sullivan air-compressor and a steam-boiler with a capacity of three tons from a depth of 1500 ft. An Anaconda hoist has also been installed in the mine.—A wage increase of approximately 25% has been granted the workmen at the Kelly mines. The increase was allowed without any labor agitation whatever, the necessity for calling a strike, or a break in the friendly relations between the employer and the employees.—P. H. Argall, the superintendent, and Ricarte Montoya carried on the negotiations, which resulted in the desired raise.

Magdalena, May 26.

OREGON

CURRY COUNTY

(Special Correspondence.)—The Blanco mine, commonly known as the Madden property, has been taken over by L. B. Newby and associates, of New York. This property, an old-beach deposit, is about half way between Port Orford and Langlois, at the foot of Madden butte. The mine was formerly worked by Cyrus Madden and was equipped with 500 ft. of sluices, with seven burlap-covered tables for saving fine gold and platinum. The gold and platinum-bearing material consists of 12 to 20 ft. of sand in which are several layers of black-sand. There is a little small gravel interstratified with

the sand, the metal-bearing strata being covered with 7 or 8 ft. of worthless wind-blown detritus. The bedrock is shale, but lies a few feet lower than the natural drainage. It is said the mine, when worked about 6 months annually, has paid over \$1000 a year, though it operates in a small way. It is the intention of Mr. Newby to put in a plant that will treat 500 tons per day, which will greatly increase the output and enable the work to be accomplished at a cost much below that heretofore obtaining. It is believed that when suitable machinery has been provided to work the sand below the level of the present natural drainage, the value of the material handled will show a substantial increase in value per ton. The property covers a large area of workable material.

Bandon, May 30.

JACKSON COUNTY

(Special Correspondence.)—W. H. Gore, president of the Medford National Bank, with several other local capitalists and a Portland auto-truck company, have submitted a proposition to the Blue Ledge Mine Co., by the acceptance of which it will be able to ship from three to five carloads of ore per day, instead of three weekly, as heretofore. The mine is situated 30 miles from Medford. The owners began shipping ore last December, employing all the available teams and trucks in the valley, paying as high as \$10 per ton for the haul to the railroad. The object is to put on about 50 auto-trucks and convey the ore from the mine to the railroad as fast as it is extracted. More trucks will be added if necessary. A feature of the plan will be to expend about \$10,000 on the road in conjunction with an equal amount furnished by the county. The total cost to the proposed truck-company would be in the neighborhood of \$50,000.

Should the development of the mines adjacent to the Blue Ledge, and in other camps of that district, as now contemplated, justify it, the new transportation company will eventually build a railroad into that region, to handle both its mine and timber output, and to use the auto-trucks on feeder-lines.

In this manner Mr. Gore and his associates hope to be able to solve the transportation problem, lack of a solution of which has so long retarded the development of several rich mining districts immediately tributary to railroad transportation in this valley.

Gold Hill, May 29.

JOSEPHINE COUNTY

(Special Correspondence.)—Eleven copper claims on Fall creek, in the Upper Illinois district, 13 miles north-west of Selma, known as the United Copper-Gold Mines property, were sold this week to R. J. Rowen, representing Eastern capital, by W. S. Low, Daniel Webster, and C. E. Lebold, of Salem. The property is an old producer and is known as one of the high-grade properties of this county. It shipped ore in the early days by way of Crescent City, and later to Martinez and Tacoma. Shipment was made by pack-horses, wagon, and railroad.

Building the new wagon-road to the chrome mine, four miles this side of the property, solves the transportation problem. The new owners will begin shipments promptly upon the completion of this road on which 165 men are employed. Mr. Rowen has also closed deals for the Katy Ayers and Emerald groups of copper claims on Rancheria and Cedar creeks, smaller and less developed properties.

Grants Pass, May 28.

SOUTH DAKOTA

LAWRENCE COUNTY

The Homestake Mining Co. has received an order for 90 tons of tungsten concentrate, one carload of which has gone out. Another car is being loaded and a third shipment will leave Lead by the middle of June. The Homestake continues to produce a high-grade concentrate. The mill is working satisfactorily and a steady supply of ore is coming from the

mine in West Lead. The old dumps have been practically cleaned up, the greater part of the ore production coming from the mine, where the veins hold out well and give promise of long continued production.

The Homestake Mining Co., having decided to pension some of its employees who, because of old age or physical disability, are no longer fitted for the proper discharge of the duties assigned to them, has sent out notices to 26 such employees, advising them that the proposed pension-system will go into effect on July 1 of this year. Eligibility to the pension-list is not based on long service with the company, as some of those who will be retired have worked comparatively few years; one of them at least having been on the pay-roll only six years.

The pensioners will receive 25% of their last year's pay, plus \$10 for each year they have been in the employ of the company; thus, a man whose total pay during the last year of his regular employment amounted to \$1000, would get 25% of this, or \$250, and in addition, if he had worked 20 years for the company, would receive \$10 for each of these years, or \$200, making his total year's pension \$450.

No pension of more than \$600 will be paid. The pensioners are not prohibited from doing work for themselves and many of them will be able to add materially to the amount paid them each year by the Homestake company.

The management of the Homestake company has compiled a census of the men in its employ who are eligible under the provisions of the selective-draft section of the army-bill. The list shows that something less than one-third of the employees, or 710 men, come within the age limits, and are divided among the different departments as follows:

Mine	488
Wood and timber	18
Machine-shops	14
Foundry	16
Homestake mill	12
Amicus mill	8
Electrical department	12
Water department	10
Blacksmith shop	10
Slime-plant	10
Assay-office	9
Survey department	7
General supplies department	6
Scattering	90

Of the 710 eligibles, 461 are single men and 216 are married. Thirty-three have not taken out citizenship papers.

TEXAS

BEXAR COUNTY

(Special Correspondence.)—C. L. Baker, who is making a geological survey of this part of the State for the Bureau of Economic Geology and Technology of the University of Texas, has discovered, near here, a large deposit of bentonite, a peculiar and valuable clay, that has heretofore not been known to exist outside of Wyoming, in this country. One of the valuable physical properties of bentonite is that it is capable of absorbing large quantities of various liquid substances. It is put to many uses, among them being in the manufacture of a medical dressing, known as antiphlogistine. Its chief use, however, is to give body and weight to paper. It is also used as a soap-filler in the manufacture of high-grade soaps; to dilute powerful drugs, that are sold in powdered form, and as an adulterant in candy. Steps are to be taken toward developing the deposit on an extensive scale.

San Antonio, May 20.

EL PASO COUNTY

(Special Correspondence.)—Unusual activity in mineral exploration and in the development of existing properties is re-

ported from the different districts of west Texas. It is announced that the Tama Silver Mining Co. recently uncovered a large body of zinc carbonate on its property in the Quitman district, near Sierra Blanca. It is claimed that the ore averages 20 to 40% zinc. The surface outcrop has been explored to shallow depth and there has already been exposed in the workings more than 15,000 tons of ore.

The Hazel Silver Mining Co., which operates the old Hazel copper mine, situated 18 miles north-west of Van Horn, will soon install a cyanide-plant. O. W. Steel is manager.

Edwards & Bright are developing a promising copper property three miles south of Allamore.

Love Bros. soon will begin making regular shipments of silver and lead ore from their mine, nine miles south-west of Sierra Blanca. The Bonanza mine, also situated in the Sierra Blanca district, is being developed by Thomas and Rowdy Love. This property has produced a large amount of high-grade silver-lead and zinc-sulphide ore. Love Bros. soon will build a 75-ton mill on the property.

The Lulu B mine, which is owned by the Lulu B Mining Co., and located in the Sierra Blanca district, is making a good showing of argentiferous lead carbonate and molybdate of lead. W. W. Crosby is manager.

Alpine, May 21.

UTAH

TOOELE COUNTY

The Deep Creek railroad has announced a new time-schedule from Wendover to Goodwin. The new schedule, which includes both freight and passenger, provides several trains each way per day. The freight-service has been adjusted to meet requirements of new machinery shipments for the Queen of Sheba, Woodman, and other properties under re-construction in the district.

J. B. Reid, mill-superintendent for the Queen of Sheba Mining Co., is remodeling the mill. He will remain on the property until he has brought it up to modern requirements.

ALGERIA

The Beni-Felkai Mining Co., Ltd., of London, has been granted a concession to carry on iron-ore mining near Taki-tount, in the Constantine Department of Algeria. The terms of the concession are reported to provide for payment to the Algerian government of a royalty of 4d. per metric ton of ore used or sold by the company.

CANADA

ONTARIO

(Special Correspondence.)—During April the Nipissing Mining Co. mined ore of an estimated value of \$259,082 and shipped bullion from Nipissing, and customs ore, of an estimated value of \$517,719, making in all a little over \$750,000. Results for the month, although devoid of unusual features, were satisfactory. The high-grade mill treated 171 tons and shipped 703,756 oz. of silver. The low-grade mill treated 5829 tons of ore. The following is a summary:

Washing-plant	\$129,792
Low-grade mill	129,290
Nipissing and customs ore	517,719

Total\$776,801
Cobalt, May 10.

The gold and silver mines of northern Ontario in 1916 paid dividends to the amount of \$76,956,790.

MEXICO

NUEVO LEON

(Special Correspondence.)—The revival of mining and smelting in Mexico is due to the restoration of peace and order in many of the ore-producing districts. The Compañía

de Minerales y Metales, which is one of the largest American owned companies operating in this country, has re-established its headquarters here, and has reorganized its working forces at its different mines and expects soon to bring its ore output up to what it formerly was in normal times.

There has arrived here a party of officials of the American Smelting & Refining Co., headed by the general superintendent, A. McL. Hamilton, of San Francisco. They will visit the smelters and mines of the company at Matehuala, the smelter at Aguas Calientes, and give attention to the details connected with the re-opening of these properties. The several plants will be in full operation, it is stated, by June 1. The work-men have been brought from Chihuahua, where they were employed in the smelter of the company near that city.

It will probably be several months before all of the twelve large smelters in Mexico are again in full operation, even should there be no revolutionary disturbances in the meanwhile. It is necessary to bring in large shipments of coke and to do this, additional equipment will have to be provided by the railroads. Coke is now being imported from Birmingham, Alabama, by way of the port of Tampico.

Before the general cessation of mining operations in this country there were being produced here approximately 160,000 tons of ore each day which required for transportation about 6400 cars. The large smelter at Torreon, which is owned by the Madero interests, has been operated from time to time during the last two or three years for the benefit of the Carranza government. It is reported that it will soon be turned over to its owners and again placed in operation.

Monterrey, May 17.

SINALOA

The Jesus Maria y Anexas, at San José de Gracia, is being operated by its Mexican owners. This is the famous gold mine formerly belonging to a company controlled by leading men in the Calumet & Hecla corporation. Guadalupe de los Reyes, belonging to a Spanish concern, is intermittently running, and the well-known Minas del Tajo, at Rosario, is milling a small tonnage, activity at both these mines being limited for want of cyanide. The Pánuco in the district of Concordia, a silver mine that has yielded large sums to its original Mexican owners, is now being worked by the Government. The only other important mines in the State which are operating are the Potrero and the Palmarito close to Mocorito. E. A. H. Tays is developing a copper mine near San Blas. Across the boundary line, in western Durango, the mines at San Dimas are treating a fair tonnage and the San Fernando is taking out shipping ore that is being sent to the Copper Queen smelter at Douglas, Arizona.

KOREA

The Oriental Consolidated Mining Co. reports the clean-up for April as \$125,000.

Underground developments at Tul Mi Chung continue to be satisfactory.

At the Suan mine a discovery of high-grade ore has been made. An average of 22 samples taken returned 15.02 dwt. gold and 2.18% copper per ton.

TRANSVAAL

(Special Correspondence.)—The following cablegram has been received at London from the head office in Johannesburg: "Annual revision of ore reserves in the Bantjes Consolidated Mines (Ltd.) has been made as at end of 1916, and gives the following results: Leader (including some Main Reef) 198,300 tons, value 5.8 dwt. over a stoping width of 44 in.; South Reef, 213,700 tons, value 5.5 dwt., over a width of 41 in.; total payable ore 412,000 tons, value 5.6 dwt. Comparing the reserves at the end of 1915, this shows a total decrease of 236,000 tons and half-a-pennyweight per ton in value.

Johannesburg, May 15.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

BEN. S. REVETT is in Idaho.

W. H. ALDRIDGE is in San Francisco.

R. L. GRIDER is in northern California.

J. PARKE CHANNING is at Portland, Oregon.

ALBERT BURCH has returned to San Francisco.

C. COLCOCK JONES was in San Francisco this week.

ALBERT L. WATERS has gone from Arizona to Philadelphia.

S. HERBERT-WILLIAMS, of Ely, Nevada, is at the Stewart hotel.

L. B. NEWBY has returned to New York from Curry county, Oregon.

FORBES RICKARD has returned to Denver from Lovelock, Nevada.

O. R. WHITAKER has returned to Denver from Chloride, Arizona.

COREY C. BRAYTON will be at Midvale, Utah, through the month of June.

W. F. STEVENS has returned to Long Beach, California, from Lovelock, Nevada.

BERNARD MACDONALD is going to Antofagasta, Chile, and will be absent several months.

H. R. NORSWORTHY has returned to San Francisco from Plumas county, California.

H. B. SHARPS, superintendent of the Big Casino Mining Co. at Searchlight, Nevada, is at Philadelphia.

EDWIN E. CHASE and son, on their return to Denver from Missouri, have gone to Yavapai county, Arizona.

ARTHUR C. TERRILL has returned to the University of Kansas from an inspection of the Augusta and Eldorado oilfields.

CLYDE R. WEED, formerly superintendent of the Lake mine, has been appointed manager of the Hancock mine, in Michigan.

R. E. VANDRUFF, president of the New Dominion Copper Co. recently inspected the property of this company at Globe, Arizona.

PHILIP N. MOORE has returned to St. Louis, having completed his visits, as President of the Institute, to the various western sections.

ALF WELHAVEN, resident manager for the Oriental Consolidated Mining Co., sailed by the 'Korea Maru', from San Francisco for Korea on June 5.

J. ED. SHARMAN, formerly with the Nipissing research staff at Cobalt, Ontario, has been awarded the D. S. O. for good work with the British Naval Flyers.

W. W. WISHON, consulting engineer for the Big Casino Mining Co., has been in Madera county, California, making an examination of the Mud Springs mine.

JOHN L. HARRIS has resigned as manager of the Hancock mine. Mr. Harris, like his father, has been long honorably identified with copper mining in Michigan.

D. D. HOMER, until February 1, general superintendent for the Butters Devisadero Company in Salvador, is now general superintendent for the Jerome Del Monte Copper Company at Jerome, Arizona.

M. L. FULLER, managing geologist of the Associated Geological Engineers, is conducting exploration work in West Virginia; C. T. GRISWOLD has gone to New York; ERNEST MARQUARDT is in Wyoming, and F. G. CLAPP, managing geologist, has just completed a monograph on oil and gas in South America.

H. A. PIPER, an engineer, long prominently identified with Rhodesian mining, notably as consulting engineer to the Globe & Phoenix Gold Mining Co., died of pneumonia in May shortly after his return to England from South Africa.

THE METAL MARKET

METAL PRICES

San Francisco, June 5

Antimony, cents per pound.....	23.50—25.00
Electrolytic copper, cents per pound.....	33
Pig lead, cents per pound.....	10.25—11.50
Platinum, soft and hard metal, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.....	\$90
Spelter, cents per pound.....	11.50
Tin, cents per pound.....	65
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, June 5

Antimony, 50% metal, per unit.....	\$1.70
Chrome, 40% and over, f.o.b. cars California, cents per unit.....	50—55
Magnetite, crude, per ton.....	\$8.00—12.00
Tin, cents per pound.....	60
Tungsten, 60% WO ₃ , per unit.....	20.00
Molybdenite, per unit for MoS ₂ , contained.....	40.00
Manganese, 45% (under 35% metal not desired), cents, unit.....	36—38

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

	Per unit
Above 49% metallic manganese.....	\$1.00
46 to 49% metallic manganese.....	0.98
43 to 46% metallic manganese.....	0.95
40 to 43% metallic manganese.....	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.25% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

EASTERN METAL MARKET

(By wire from New York)

June 5.—Copper is strong, with prices nominal at 32.50 to 32.75c. Lead is strong and advancing at 11.37 to 11.50c. Zinc is quiet and firm at 9.75c. Platinum is unchanged at \$105 for soft and \$111 for hard.

SILVER

Dividends declared by the large copper companies in May were over \$10,000,000, which was an increase of \$3,400,000 over the dividends of May 1916. This was due chiefly to the fact that the United Verde Extension, the Shannon, and the Mass companies have joined the list of dividend payers since May 1916.

TIN

Prices in New York, in cents per pound.

	1915	1916	1917		1915	1916	1917

May.....	75.00	90.00	104.00	Nov.....	101.50	79.50
June.....	90.00	74.70	Dec.....	123.00	80.00

Quicksilver has been exceedingly dull with very little business, and prices have been reduced to \$90 per flask for virgin Californian, with Mexican selling around \$85.

Platinum is quoted at \$105 for soft unalloyed metal and \$111 for the hard natural platinum-iridium alloy.

Tungsten: The past week has again seen considerable business in tungsten, and the New York market is practically bare of supplies for early deliveries. Not only our home market but foreign markets have again appeared as buyers, but it has been impossible to quote against all the inquiries received. The market is quite firm at schedule prices for American scheelite, with foreign ores of good quality selling at \$20. The inquiries for ferro-tungsten for home consumption from Canada, Italy, and France are for very large quantities and the price rules firm at \$2.25 to \$2.50 per pound.

Molybdenum: Molybdenum ores continue in demand and business has been done at \$2 per pound MoS₂ for 90% concentrate.

Manganese remains firm and in strong demand with \$1 quoted for furnace-ore and 5 to 7c. for high-grade chemical ore.

The annual report of the International Nickel Company for the year ended March 31 shows earnings of \$17,000,000 after deducting the cost of manufacture, selling and maintenance charges. Net profits of \$13,558,000 enabled the payment of over \$10,000,000 in dividends and the addition of \$2,982,000 to surplus account, thereby increasing that item to \$6,200,000, a figure nearly double the amount standing at the end of the previous fiscal year. Although more liberal in publicity than ever before, the management has never brought its annual reports up to date in the matter of information concerning actual operations. The International Nickel Co. looms as the largest nickel producer in the world, yet no idea as to its output of that metal ever appears in official data. The company also ranks among the largest copper producers of the Dominion of Canada, but no figures of production have ever been made public.

Cost items, such as make the perusal of a mining company report worth while, are conspicuous by their absence.

The attempts made lately to place further orders for ferro-manganese have elicited the fact that sellers have practically vanished. British producers are heavily sold ahead and it is much more difficult than before to obtain licenses. Inquiries are still coming in on Continental and trans-Atlantic account, but business is almost impossible. The tendency is undoubtedly much stronger, with f.o.b. prices for loose ranging nominally from \$10 upward. Bids of \$41 and more from Spain have been refused, and it is impossible to furnish reliable quotations. There is a small business passing in Indian manganese ores, the negotiation of orders being handicapped by tonnage difficulties.

Eastern Metal Market

New York, May 29.

The principal metals continue to maintain their strength and most of them have advanced.

Copper is stronger with a firm undertone.

Zinc is steady and strong but not active.

Lead is very strong and advancing each week, with supplies rather limited.

Tin is quiet but strong with anxiety lessened by fairly large arrivals.

Antimony is easier and somewhat lower.

In the steel market the enormous volume of the purchases of steel by the Government is causing prices to go higher for the manufacturing consumers. The needs of the Government for sheets is larger than figured, and these have advanced about \$5 per ton during the last week. Considerable interest is manifested in the coming award by the Government of contracts for 7,500,000 shells for field artillery, requiring about 50,000 tons of steel. A falling off in the needs of automobile companies for steel has materialized, makers of pleasure-cars having requested the holding of shipments in some cases, but Government buying of motor-trucks embraces 70,000 now under inquiry and more to come. Deliveries of nearly every form of finished steel become more difficult each week, as the Government demands preferential treatment for the movement of coal and iron ore.

COPPER

The market is growing stronger instead of weaker, despite the fact that very few sales are reported. Quietness generally prevails, and conditions are decidedly uninteresting. A little business in June-July delivery has been done, but the volume was not large. The metal is really scarce this side of August, and obtainable only from second hands, with many producers out of the market for June and July shipment. It is estimated that 5,000,000 lb. was sold last week for this position through dealers and outside holders, but this has not been confirmed. For metal desired after August 1, prices have stiffened if anything, third quarter being quoted at 30 to 31c., New York, for electrolytic, with July metal higher at 31 to 32c. The market is still influenced by the Government's probable needs and policy. No purchases from that source have yet been made, it is believed, nor are any expected for several weeks. Without doubt the impression is gaining force that each government will fare the same in its purchases, and that these will be made nearer the current level than in the case of the first lot sold at 16½c. per lb. The quotation today for nearby Lake and electrolytic is 32.50c., New York. The London market for spot electrolytic is apparently unchanged at £142, the last quotation made on Saturday, yesterday having been a holiday there.

TIN

Opinion in the trade as to whether the proposed Government duty will be put on tin seems to be divided. Some think a duty of fair proportions will be levied, but the majority appear to contend that tin will finally come in free of tax or duty. The market is quieter than for some weeks, and transactions have not been many nor large. There is an absence of feverishness and anxiety. This condition is due partly to the fact that arrivals have been more plentiful recently. The total to May 28 for the month was 5295 tons, a generous amount, and larger than in some time. The quantity afloat was 1977 tons on the same date. In general, dullness has prevailed most of the past week. On May 23 there were a few sales of spot tin at 65.50 to 65.60c., with a few sellers at 65.25c., New York. On the same day Banca tin was sold at 63c., ex-steamer at dock. On May 24 spot Straits tin was sold at 65.40c., with offerings at 65c. Spot Banca on the same day was offered at 62.50c.,

New York, but there were no buyers. On May 25 the price fell off to 65c. where it still was yesterday, with the market dull and flat. Yesterday there was no business and the market was stale. The general halt in activity is largely due to conditions at Washington. The London market is still strong, the last quotation having been £253 17s. for spot Straits on Saturday, May 26, yesterday having been a holiday in England.

LEAD

The lead market is the strongest of all the metals and continues to gain in strength each week. In the past few days prices have risen steadily on moderate sales, due to a fairly large demand, but with supplies relatively small to meet this. Most of the large producers continue out of the market, because of the uncertainty as to just how much the Government is to require. Until this is settled, conditions will remain more or less as they are. High prices usually curtail consumption, but under the present abnormal or war-conditions this will prove an exception, and the effect on business will probably be of little consequence. Some Mexican lead was sold during the last week, and a fair business has been reported in it. It went at full prices in bond. It was looked upon with favor for export purposes as the price was under domestic metal because of duty-questions. One dealer reports selling a car-load of domestic lead at 11.50c., New York, yesterday to a jobber. The quotation today was 11.22½c., St. Louis, or 11.37½c., New York, a slight advance over yesterday.

ZINC

The market is firm with futures higher than spot or nearby metal. This is due partly to the strong ore situation, but largely to the attitude of the large producers. As high as 9.50c., St. Louis, has been bid and taken on June-July shipment of prime Western, though ¼c. under this is also reported for this position. The nearby market is very quiet at from ½ to ¾c. under the quotation for future delivery. Demand for any position is very light, though some sales are reported. The expectation is that not much activity is likely until the Government's needs are more fully known. Exports for April, as far as reported, total 9617 tons.

ANTIMONY

Demand has fallen off somewhat and the market is easier at 24 to 25c., New York, duty paid, for Chinese and Japanese grades. The demand for future delivery is reported as good, with prices firm, and at higher levels than in some time.

ALUMINUM

Some interest is taken in the personnel of the aluminum committee of the Council of National Defense. It is: Arthur V. Davis, president of the Aluminum Company of America; E. E. Allyn, president of the Aluminum Castings Co., Cleveland, Ohio; Joseph A. Janney, of Janney, Steinmetz & Co., Philadelphia. The market is unchanged at 59 to 61c. for No. 1 virgin metal, 98 to 99% pure.

ORES

Tungsten: The market has changed but little since last week. Demand is light and quotations are about the same. The official price for 60% concentrates is \$20 per unit. Ferro-tungsten is quiet, with the quotation at \$2 to \$2.15 per lb. of contained tungsten, though some are asking as high as \$2.35 per pound.

Antimony and Molybdenum: These ores are unchanged from last week, and the demand is very quiet. It is stated that there is a growing recognition in this country of the value of molybdenum steel for ordnance purposes.

EDITORIAL

T. A. RICKARD, Editor

IT IS high time to cease speaking of *the* Allies and *the* War in Europe; it is *our* Allies that are fighting splendidly for a cause to which we are now committed and to which we are already contributing greatly. Unless we make it *our* War it will be *our* defeat, a word not yet in the lexicon of American democracy.

DETERMINATION of lead by a volumetric chromate method is discussed in this issue by Dr. John Waddell of the School of Mining of Queens University, Canada. The method was proposed some years ago by Mr. H. A. Guess, but the elaboration of the details by Dr. Waddell has increased its accuracy so as to give it marked advantages, especially for low-grade samples, over the molybdate method.

OUR allies need 1,400,000,000 pounds of copper this year, we are told; while our Government will require 250,000,000 pounds, with another 100,000,000 required early next year. The production of copper in the United States is now at the rate of 1,800,000,000 pounds per annum, so that more than an adequate market seems assured, since provision must be made also for our ordinary domestic consumption, which is increasing.

A MINING ENGINEER from Colorado called upon Mr. John Ballot, chairman of the Minerals Separation company, in London, to obtain a license to use the froth-agitation process. When he was told that the plant was to have a capacity of only 100 tons daily, Mr. Ballot refused to grant a license or to bother about the business. That shows the spirit of these patent-exploiters. Are they to have the right not only to issue permits but to refuse a permit at will?

MEXICAN stocks are strong on the New York exchange, owing to quieter conditions in Mexico and the resumption of operations by the American Smelting & Refining Company. At El Paso the opinion is not so optimistic. The leopard can only change his spots by being compelled to move. No loan to the Mexican government is to be made either by our Government or by our banks. Carranza is flirting with the Germans and Obregon is touring the country with German officers in uniform. We know how much to trust the shifty gentleman on the other side of the Rio Grande.

IN our issue of April 7 we discussed mining by the State, with particular reference to the Transvaal, where this socialistic idea was then under serious con-

sideration. On April 21 the majority report of the South African State Mining Commission was published at Johannesburg. Three members of the Commission voted against the proposal and joined in advising the Government that it should not engage directly in the mining of any minerals; the two other members wrote separate reports expressing their divergent opinions. Both, however, advocate State control of the mining and marketing of diamonds. The mining industry of the Rand is to be congratulated on the exorcising of this bogey.

OUR New York contemporary has been misled by irresponsible newspaper chatter into writing some cheap stuff against Congress, five times repeating the silly slogan, "The people want you to come home." The writer of such balderdash ought to know that under a system of representative government it is customary and necessary for the national legislature to ventilate opinions and to give public expression to the ideas of a democratic community. The Administration has done well, but it would be a gross political blunder to send Congress home with the idea of leaving the President and his cabinet uncontrolled by such public opinion as the legislative authority is authorized to express. There has been a good deal of talk in Congress, and some of it may seem unnecessary, but the volume of speech has not been out of proportion to the importance of the matters discussed. The idea of treating Congress as if it were a wearisome superfluity is undemocratic and it is childish.

METAL MINES rarely experience calamities so costly in human life as the conflagration in the Speculator mine of the North Butte Mining Company, where more than 60 men are known to have perished on Saturday last. It is feared that the death-roll may swell to 150. The helmet-men of the mines-rescue organization did splendid service, but in the lower workings, on the 2200-ft. level, they found gases so dense as to render their equipment inadequate, thus seriously limiting their effort at relief. As often happens, the crisis developed a hero, a tool-boy, Manus Duggan, who will have honor in the annals of Butte. The fire is said to have been caused by the ignition of frayed cable-insulation by the heat from the flame of a carbide-lamp. The shaft-timbering intensified the difficulties, and points to the need of employing concrete or metal framing in working-shafts of such importance. Two men were caught in the cage above the flames, unable to signal because the wires attached to the timbers had been destroyed; and the shaft presently began to cave as the supports burned away.

Whether blame may be directly attributable to anyone we do not know, but lessons will be learned from the disaster that must lead to safeguards for the future.

AT the annual meeting of the Institution of Mining and Metallurgy, it was voted, unanimously, to send the following telegram to the American Institute of Mining Engineers: "The Institution of Mining and Metallurgy, assembled in London in annual general meeting, sends fraternal greetings to the American Institute of Mining Engineers, and rejoices in the new bond of friendship and unity of purpose between the two societies resulting from the great historic act of participation of the American people in the war of freedom and civilization against military autocracy and barbarity." The prompt reply was as follows: "Your cordial greetings much appreciated by American Institute of Mining Engineers, whose board of directors at its meeting last evening responded with sincere wishes and statements that the members of our body are doing all in their power to hasten active participation with our Allies. (Signed) Philip N. Moore, President; Bradley Stoughton, Secretary." The mining engineer may be a good deal of a cosmopolitan, but his cosmopolitanism is of a selective kind, and in this crisis of civilization he has no trouble in deciding how to align himself. In mining, as in sport, and in sundry other matters even more important, we Americans are glad to stand shoulder to shoulder with the British and French. Out of evil may come good, and one of the chief blessings of the War is this comradeship between the democracies.

MINERALS SEPARATION has collected \$1,115,500 in royalties during the last two years, so says the *Boston News Bureau*. The first American company to take out a license was the Inspiration, in April 1913. By the way, we can state that the Inspiration-Anaconda contract does not run indefinitely; it expires with patent 835,120, namely, on November 6, 1923. On that date the two copper companies regain freedom of action. The other licensees are said to be the Consolidated Arizona Smelting Co.; Atlas Mining & Milling Co., Elm Orlu Mining Co., Old Dominion Co., Mountain Copper Co., Weedon Mining Co., St. Joseph Lead Co., Cananea Consolidated Copper Co., Arizona Copper Co., Doe Run Lead Co., Utah Leasing Co., Colusa Parrot Mining & Smelting Co., Goldfield Consolidated Mines Co., Ducktown Sulphur, Copper & Iron Co., Britannia Mining & Smelting Co., Mond Nickel Co., Cuba Copper Co., Standard Silver-Lead Co., Braden Copper Co., and Phelps, Dodge & Co. At least one of these has refused to sign a contract and others have tied themselves not too firmly. The Minerals Separation people assert that 35,000 tons of ore is treated daily by those they call infringers, meaning non-licensed operators. This is equivalent to 12,500,000 tons per annum, and it is a conservative estimate, for everybody that uses flotation does not notify either Dr. Gregory or Mr. Nutter. If 15,000,000 tons is treated by non-licensed operators this year, the royalty,

at 10 cents, would be \$1,500,000; but even that does not measure the tribute to be exacted. The group of copper mines under Mr. Jackling's management will produce 600,000,000 tons in the next 30 years; at 10 cents that means \$60,000,000. The stake involved is big enough. Next, consider the oil consumed; if that absurd 'critical' proportion is to be the limit of the Minerals Separation embargo and 20 pounds more is to be consumed to prove that the Supreme Court was deceived, then in 1917 we shall require something like a million barrels of oil for use in the flotation mills of this country. The amount of oil consumed annually would generate 46,000 horsepower continuously and the production of it would entail the destruction of 800,000 cords of Southern pine. These are figures big enough to emphasize the fact that the claims of Minerals Separation trespass seriously on our national resources.

Colorado School of Mines

This technical institution has been the unfortunate victim of a flasco that is not without its wider bearing on the education of young men in other States. We have taken pains to ascertain the facts, hoping that our unbiased comment may interest the alumni of the school and also the profession at large. On April 23, which was Senior Day, the customary fun was carried too far. Several seniors and many sophomores were drunk by the time the base-ball game was begun. A member of the faculty was 'wrinkled,' which is a form of hazing particularly repulsive to a man with any self-respect. The students were more unruly than usual, the police-court verdict of 'drunk and disorderly' being adequately descriptive. At the subsequent meeting of the faculty it was decided to suspend five students for one year and to reprimand others. When the suspensions were announced the student body protested and later decided that "the three lower classes would quit school as individuals." The seniors wished to follow suit, but it was decided that it would be a serious mistake for them to miss graduation. The president of the School, Mr. H. C. Parmelee, addressed a meeting of the students. He showed commendable firmness. Mr. Parmelee had been a trustee before being appointed—a year ago—to the presidency of the School. For both positions he was endorsed heartily by the Colorado Scientific Society, and he is receiving the cordial support of the mining profession in Colorado, more particularly the alumni of the School. A committee of the students met the board of trustees, who then recommended the faculty to re-consider the case. A committee of local citizens—at Golden, where the School is established—interfered and called upon the Governor of the State to take a hand. He sent a trustee that he had appointed eight months previously, Mr. A. E. Carlton, who had not attended a board meeting up to that time. Mr. Carlton assumed an intelligent attitude, but immediately thereafter he resigned. Matters drifted. The students returned to their homes. At the commencement, on May 25, only the graduating seniors were pres-

ent, besides the alumni and general public. Last term the School included 175 students, of whom 30 were seniors. Its governance is in the hands of five trustees. Here is where the trouble begins. The trustees are not elected; they are appointed by the Governor. One of them is a reporter on a Denver paper, a man as unfit to direct the administration of an educational institution as he would be to direct an astronomical observatory; another trustee is a small banker at Golden, also without special qualification, but, of course, extremely anxious that the attendance at the School shall be maintained unimpaired for the benefit of the local boarding-houses and trades-people; the third is a banker and financier, already mentioned, one of the big men of Colorado, a clever and energetic man, but so immersed in his own affairs that he has no time to attend to his duties as a trustee, an appointment he should never have accepted; the two other trustees are unexceptionable, both being graduates of the School and mining engineers of excellent reputation, Messrs. O. R. Whitaker and F. W. Willis. In short, the board of trustees contains two that are fit for their duties and three that are unfit. That is sufficient reason for the chaos. Another is the manner in which the local press treated the affair. Denver, like San Francisco, suffers from its miserable newspapers. The *Post*, like our *Examiner* and *Chronicle*, is mean, malicious, and misinforming. The *News* is feebly respectable, but even this less vicious paper injured the Colorado School of Mines by the piffle that it has published during the past month. Another factor is the laxity of discipline at Golden. To the students the action of the faculty, in suspending the five students, seemed severe because they were unaccustomed to proper control. They had the cheek to say that they would return "when the faculty would promise to work in harmony" with them. This reminds us of the telegram sent by a State Senator to the Governor of Colorado when, in 1903, the strikers had driven the Smuggler-Union miners, by the free use of bullets, out of the Bullion workings. The sapient legislator reported to the Governor: "The strikers are now in peaceful possession of the mine." So now the students ask for a faculty that will continue in peaceful subservience to them. What they need is military discipline. Disloyal to their alma mater, which they have brought into ridicule, mutinous to their teachers, reckless of their careers, how can they expect to become fit to direct the work of other men in mines and mills if they themselves exhibit so little self-control? We hope that the president and faculty will not make the egregious blunder of giving way in this crisis by allowing the students to return at will. They should be required individually either to make an apology or to express regret for their conduct. If not, the tradition of unruliness will be perpetuated and the seed of future trouble will be re-sown in the School.

The Colorado School of Mines is 43 years of age. It has had a chequered career, owing to lapses in administration, but it has furnished the American mining industry with a large number of capable men. It ranks

with the Michigan College of Mines as a technical institution, lacking academic distinction it may be, but effective in training engineers and metallurgists of a forceful kind. The School has performed the work for which it was created and deserves to be supported both by the State and by the mining profession. The annual appropriation is \$95,000. That does not seem too much. Nevertheless there has been talk of tacking the School to the State University at Boulder, so as to end the frictions and fusses that have disfigured its record. Whether that step is advisable, we do not know; it is one that should not be taken without asking the opinion of the alumni, in the first place, and of the mining profession in Colorado. We urge the local section of the American Institute of Mining Engineers at Denver to take an interest in the matter and to do its best, collectively and individually, to support the School, so that it may continue to be a seat of education, social as well as scientific, in the great mining region of Colorado.

Sulphur and the Food Supply

The article contributed to this issue by Dr. P. J. O'Gara, the director of the agricultural experiment station maintained by the American Smelting & Refining Company near Salt Lake, Utah, is a message full of significance for the nation at this period of stress. We must feed England and France as well as our own people; we must feed an army that will grow from month to month until it will number millions of men; we must feed an increasing horde of workers in the factories. It is estimated that this industrial army alone will need to be augmented more than 25% within the coming year in order to provide the multitudinous supplies that will be required in the conduct of the War. Although women will supply the call for labor to some extent, the fact remains that there will be fewer men available to produce the food that is essential for sustaining the nations warring to preserve the institutions of liberty. The call from Washington to make every lawn into a garden, to turn every boy into a producer of potatoes and beans and corn, is prompted by a clear vision of the insufficiency of farm products that we are facing. We must have enough food to supply our vital forces or we shall weaken, and that means disaster.

The lesson that Dr. O'Gara teaches is that sulphur will make one man more than the equal of two in the raising of wheat, and the equal of four in the raising of peas, to name no other crops. It appears that elemental sulphur used as a fertilizer, at the rate of from 300 to 400 pounds per acre, is an energetic stimulant to nearly every variety of crop. As compared with untreated lands the increase of yield is from 63% for potatoes to 383% for peas. The grains are all strongly responsive to the influence of sulphur, especially on soils that represent the decomposition-products of granitic rocks, but the most amazing effects are produced with the leguminous plants. Dr. F. C. Reimer, of the Southern Oregon Experiment Station, has shown that

the cut of alfalfa can be increased in some cases as much as 500% by harrowing 300 pounds of raw sulphur into each acre. Equivalent improvement is obtained with beans and other legumes. To achieve such results is like multiplying the land, and is even more than multiplying the tillers of the soil, for it represents an increase in production without more mouths to feed. The American Smelting & Refining Company has done a great service in applying the methods of the trained technologist to demonstrate that the smelter not only should live as the harmonious contributor to the welfare of his agricultural neighbors, but that the farmer needs him as a resource for the sulphur and sulphuric acid with which to improve his soils and increase his net returns. We pointed out a few weeks ago the splendid work of Dr. C. B. Lipman, of the California Experiment Station, in reclaiming alkali lands by the use of sulphuric acid. This in itself showed that the old feud between smelter and farmer was coming to an end. The employment of elemental sulphur, however, extends the possibilities for both. Sulphur has a wider range of usefulness; it is adapted to soils to which the addition of acid would be undesirable; it is suited to the conditions of Georgia, or Virginia, or New Jersey, as well as to the alkali lands of the Salt Lake basin or the San Joaquin valley. It may be said that the one important limitation upon the adaptability of sulphur is that it may produce acid soils unless sufficient lime be present. The use of lime and sulphur together is indicated where there is a tendency to sourness. Gypsum is also a stimulant to the bacteria that promote the nitrification of soils, so necessary to the active growth of beans, peas, clover, and alfalfa; and it also shares with lime, to some extent, the function of flocculating or 'loosening' loams that are heavy with clay. The presence of abundant lime is necessary to provide base for the excess of acid formed in the process of bacterial nitrification, which otherwise would stop. Also, an excess of base must be present to take care of the sulphuric acid produced by the bacterial oxidation of the sulphur, in order to yield the neutral sulphates, in which form only the plant can take the sulphur into its circulation. All this suggests possibilities of utilizing readily available raw resources of sulphur and gypsum to increase our food-production immediately, without waiting for the smelters to get ready to turn out elemental sulphur and sulphuric acid in quantities adequate for yielding the prompt results that the nation demands.

It is desirable, before approaching that side of the subject, to call attention to a fact that had been overlooked until recently concerning the needs of plants. Determinations of the sulphur in their composition had been based upon analyses of the ash, which showed insignificant quantities of that element. It was then discovered that sulphur was present in surprising amount in the form of volatile organic compounds, and perfected methods of analysis have now demonstrated that sulphur enters into the composition of many plants of high economic value in even greater proportion than phosphorus, potash, or nitrogen. The story of Dr. Reimer's investi-

gations, following a method of elimination which finally proved that it was the sulphur that gave the stimulant needed by some of our most useful crops, possesses the quality of romance. He found that alfalfa holds in its tissues seven pounds of sulphur per ton of dried cut, while it contains only five pounds of phosphorus. Rape is still more remarkable, secreting in its tissues 20 pounds of elemental sulphur per ton. All plants require sulphur in some proportion, and even where the amount absorbed is not large, as in the case of cereals, the gradual formation of sulphuric acid, by oxidation of the sulphur, accompanied by the liberation of hydrochloric acid from the chlorides present, causes decomposition of the silicates with the ultimate production of sulphates of the alkalis. Thus the potash in feldspathic particles, which are particularly abundant in soils derived from granites and in the great areas of residual soils covering the pre-Cambrian rocks that stretch along the Atlantic coast from Pennsylvania to Georgia, is liberated in soluble form as a result of adding sulphur.

The agricultural experimenters possess the progressive qualities and also the conservative limitations that are characteristic of highly trained research-technologists. They have demonstrated the possibilities of utilizing sulphuric acid and elemental sulphur to cure the defects of excessive alkali, and to stimulate productivity to a degree that seems marvelous. They have done more than merely to show how to turn smelter-fume from a cause of litigation into the greatest boon the Western farmer has been offered, next to the waters for irrigation. They have revealed how suddenly to multiply many-fold the food-resources of America. With the modesty characteristic of accomplished scientists they hesitate to insist upon energetic action until their field-tests shall have repeatedly confirmed in every detail the results obtained; but the country needs to utilize what they have discovered and to do it now. These men have shown that plants need sulphur; that to supply it increases their growth at an enormous rate; they have shown that the sulphur promotes the nitrification of soils when sufficient alkaline sulphates are present; they have demonstrated that the readiest solution of the potash problem in its more acute phases is to add sulphur, which results in releasing the potash in a form requisite for plant assimilation, while the sulphur supplied gives the lusty deep green significant of a healthy and vigorous growth. We have found lately a great potential resource of potash in the cement and iron-furnace plants of the country. This can be rendered available more quickly under a military mobilization of our resources than would be possible through the partial re-construction and elaborate additions necessary for recovering elemental sulphur and sulphuric acid from our great copper-smelting plants. In a year or eighteen months they might be yielding large amounts. Meanwhile sulphur is immediately available from natural deposits, close to transportation conveniences, in several western States. At Thermopolis and Cody in Wyoming it has been found in limestone, associated with travertine and gypsum, and can be excavated in open quarries. In

the San Rafael canyon in Utah is another deposit of similar type, having a greater preponderance of gypsum. In El Paso county, Texas, near Guadalupe and Toyah, is an area nearly 50 miles in length and over 15 miles in width where gypsum beds impregnated with sulphur to the extent of from 10 to 20% occur in multitudinous outcrops, and where many large areas exist from which sulphur-bearing gypsum three to four feet thick can be obtained by removing less than three feet of overburden. In the same district are earthy deposits, containing more than 50% of gypsum, and 25% of sulphur, that have been explored to depths of 40 feet. Feeble efforts have been made to extract sulphur from all these deposits, but the great opportunity that they offer is that of pulverizing and shipping the material as it is for direct application to soils in order to increase the yield to meet the demands of the present crisis. The contained gypsum and lime would be helpful, as we have shown, in promoting conditions favorable to the increased growth of plants. What would be the effect of a single million tons of the crushed rock with 15% sulphur? It would amount to 20,000 carloads, which, incorporated into wheat-lands in the autumn, would add apparently more than 15 million bushels to next year's crop. It would increase the crop of beans from a million acres by 2,000,000,000 pounds; it would multiply the output of peas from that area by 5,000,000,000 pounds. Is it not worth trying? We shall soon expend more money than this would involve in the mere testing of new devices for warfare. It may not do all that we hope, but intelligently directed it can be counted upon to more than double the yield of the acreage that can be reached with the sulpho-gypseous output from the sources mentioned. A militarized nation will not hesitate; it will commandeer the men who know how to find and distribute and utilize these natural resources of combined sulphur and gypsum to help in feeding the men that are fighting for our country. Thus one part of the problem of providing sulphur, fixed nitrogen, and soluble potash, can be solved without delay. It can be made to affect some of the late crops of the present year. Meanwhile the Government could take a hand with the American Smelting & Refining Company and other smelters to insure that a sufficient output of by-product sulphur for agricultural purposes will be provided for the future.

Millions in Bubbles

This is the title of an article in the *Boston News Bureau* and it serves to emphasize the importance of the flotation litigation; but to our mind even more than millions of dollars is involved: nothing less than the self-respect of an industry. The question is whether the mine-operators of America are to be domineered by an exacting monopoly and whether the profession is to pay not tribute but subservience to a group of patent-exploiters. As our readers know, we do not believe that Minerals Separation either invented the process of flotation or developed it to its present state of efficiency.

They contributed to both, and they are entitled to some credit for both, but not to the extent of holding up the mining industry or of tying the metallurgical profession to their chariot-wheels. We note that our Boston contemporary assumes that the Miami company must pay \$4,000,000 and the Butte & Superior \$18,000,000 in damages to Messrs. Ballot, Gregory, et al. Not yet. The representatives of Minerals Separation in San Francisco have celebrated their latest legal victory in proper gastronomical fashion, accompanied by bubbles of carbon-dioxide in an amber vintage, but we believe the celebration to be premature. We hope so. The gentlemen of the Miami company are by no means depressed, for they believe that the Philadelphia decision is no final legalization of royalty-hunting. Mr. Nutter may exclaim that he is after blood, of a yellow color, referring to standard currency and not the veins of our friends, and Mr. Ballot may clench his fist and swear that he is going to bring the so-called infringers to his feet, but the end is not yet. The new suit recently begun at Butte will re-open the whole litigation and in the new record there will be written much evidence of a decisive kind that did not exist when the Hyde and Miami suits were heard in the courts of first trial. Truth will prevail, if the leaders of the industry are not stampeded into a compromise. The Supreme Court may have been hocus-pocused into the idea that a 'critical' proportion of oil is necessary for flotation as now carried out, but the operation of 1000-ton mill-units has proved that the idea of a critical factor below 1% is mythical. In the same way the fallacy of measuring the oil in ratio to the 'ore' has been swept into the limbo of absurdities, for it is known and demonstrable that the proportion of oil is determined by the amount of work it has to perform, which is dependent directly upon the weight of mineral, usually sulphide, in the pulp, and after that upon the degree of dilution and aeration. Indeed, before the litigation is done, it is more than probable that oil, as such, will not be used, because other agents for the purpose of froth-making will have come into practical service. The fact is that the Minerals Separation people, who stumbled upon a valuable idea in consequence of the work done by others in the Central mill at Broken Hill long before the pseudo-miraculous discovery said to have been made in London in March 1905, had rudimentary and incorrect ideas of the principles underlying the process when they set out to collect toll from the mine-operators. Since then great improvements have been made by others, and it is to these improvements, in machinery and manipulation, particularly the latter, that the process owes the greater part of its success. The credit that belongs properly to Minerals Separation has been discounted by their arrogance and greed; it is our earnest hope that they may be prevented from placing a tax on the industry as they have failed ignominiously in placing an embargo on technical information. In this issue we reproduce the majority opinion of the Circuit Court of Appeals in the Miami case; next week we shall give our readers the text of the dissenting opinion.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Home Vegetables

The Editor:

Sir—It has come to my attention that certain of the mining companies throughout the United States have officially taken up for their employees, the wives of employees, and children, plans for the growing of vegetables in the yards of the workers and even on vacant land owned by the companies. Some of the companies have even gone to the extent of supplying, either free or at cost, fertilizer and seeds, and also made provision for the plowing of the ground at actual cost. In other instances the companies have offered prizes for the best gardens of \$25 for the first; \$15 for the second; \$10 for the third, and a number of minor prizes, with the result that a great amount of patriotic enthusiasm has been aroused.

I have been so impressed with the starting of such a movement, modest as it is at the present, that I feel it to be my patriotic duty to urge upon all mining companies, where the conditions are favorable, to start some similar plan that would in the end result in a vast increase in the amount of food products raised during this time of national emergency.

War today is as much a matter of food supplies as actual fighting in the trenches. The man or woman or child who raises enough vegetables this summer in his garden to feed the family places at the disposal of the men at the front fighting for a world democracy just that much food.

The growing of these vegetables has also the additional virtue of giving healthful outdoor exercise to the people and for their consumption vegetables which are fresh. Back of all this you are helping to maintain the soldiers and the less fortunate populations of the world that have been thrown out of their natural orderly life by the encroachment of the war upon their properties.

The Department of Agriculture is enthusiastically in favor of this movement and has prepared for the use of those interested Farmers' Bulletin 255, 'The Home Vegetable Garden,' which will be sent to anyone who makes application. This pamphlet has already proved of valuable assistance to those engaged in making a garden. I take pleasure in sending to you under separate cover a copy of the pamphlet, to that you may see its value in this work.

It is suggested that those who join this garden movement shall place in their gardens an American flag as a reminder that he who serves his country in this capacity serves the flag.

FRANKLIN K. LANE.

W. A. Farish

The Editor:

Sir—In a recent issue of your paper, I note with regret the death of W. A. Farish, on the 4th inst., at Los Angeles. Fifty years ago and more, I knew him well, he being then manager for Ferdinand Reis, the owner of Sierra Buttes mine at Sierra City, Sierra county, and not Plumas, as stated in the obituary. This mine was noted for its pockets, four of which were struck in my time, but all by chance. One yielded \$15,000, another \$20,000, and two \$60,000 each, one of the latter being the Monumental, which furnished the big nugget you mention, and which weighed 106 lb. All of these four pockets were emptied almost at the surface, and at the slightest possible expense, but doubtless many more would have shown up, were it not for the dense growth of manzanita, chaparral, and wild plum bushes which cross the ground. It was only as a very young man that I ever knew Mr. Farish, yet I cannot but think that to his associates of later years he was the same 'Billy' Farish as to his friends of long ago.

W. W. PHILLIPS.

Interview With Henry C. Perkins

The Editor:

Sir—While ordinarily not interested in the interviews appearing in the MINING AND SCIENTIFIC PRESS from time to time, on account of the narrow limits within which the discussions are confined, subordinating, as it were, the principles by which progress is to be made to individual accomplishment in the past, I cannot but feel that Henry C. Perkins, in your issue of May 19, has touched on phases of development that should at the present time, and must in the future, enter more fully into the business of conducting enterprises of magnitude. His brief analysis of the relative latent abilities of different races and peoples under similar circumstances and with the same facilities for development are so apt, so true, and so unerringly stated that they must be apparent to all unprejudiced minds. One-half of the world is now at death-grip with the other half for no other reason than that a 'superman,' begotten by the false ideals of one, was sought to be foisted on the other. Now, if the superman is a false ideal for mankind in general it must, von Bernhardt *et al.* to the contrary notwithstanding, be false as between nations and individuals. I can unhesitatingly say this is the case with Mexico, but as long as the white man continues to sow the wind by his injustice, dishonesty, and overbearing, he will con-

tinue to reap the whirlwind in dissatisfaction, disloyalty, revolution, and crime. When the common good, as between those that employ and those that are employed, ceases to be a factor in a business management, that enterprise is drifting dangerously near to destruction. The fatal day, by fortune or the strong hand, may be warded off for a time, but each one has seen, among undertakings that have come under his individual observation, that the law of compensation holds as inexorably in the realm of business as in the realm of philosophy. Technical publications can do more to teach this basic truth than any other medium, because it will be accepted from them, not as an evanescent dream, but as the foundation of progress, of business, and, last but not least, of profit.

Douglas, Arizona, May 24.

J. H.

Crowder-Elmore—Flotation

The Editor:

Sir—In your issue of February 24 you publish under the above heading a letter of Mr. H. D. Crowder which requires certain explanations and corrections I am able to furnish; but before giving these I must protest against the manner in which you have treated certain conflicts between the statements of Mr. Crowder and facts given in my historical note of the flotation process published by you on September 23. Not only have you constituted yourself a judge in the case, which might have been expected perhaps as natural in a journalist, but you have taken on the duties of jury and executioner as well, and have pilloried both my brother and myself in a most unjustifiable manner; and you have been more hasty and inaccurate in the statement of evidence and drawing of conclusions than is allowable in a scientific journalist.

With all that has been written about the development of the 'flotation process,' and even going no further than my own historical note, it is incredible that such muddle-headed argument should still be coming up as in your article and Mr. Crowder's letter about the actual invention of that process. All the world should know by now that several inventors, at various dates, and quite independently, worked at it. Mr. Crowder senior says of Mr. Robson: "By accident he picked up a can of oil, and as he said, almost absent-mindedly tried to concentrate some of the ore. This is the true genesis of the oil process." Exactly how he tried is set forth in his patent specification, and in descriptions of his attempts by others, and is described in my historical note. Mr. Crowder states that he wrote to me in July 1899 (a year after the date of my brother's patent) giving hints on how oil might be tried; and one way was the "introduction of oil into the launder feeding the vanner" to "wet the float and carry it to a definite division." Well, Messrs. Stewart, Morris, & Richardson took out a patent in Australia in August 1895, one element of which was dropping oil into a tailing-launder below amalgamated plates, and providing the launder at its lower end "with an adjustable thin steel plate to allow the tailing to pass beneath it, while the greasy water and oil will pass above

it." That looks very like an anticipation of Mr. Crowder's idea of wetting the float and carrying it to a definite division; but it does not prove robbery on his part. There is also no evidence that Robson got his oil can absent-mindedly from Carrie Everson's pudding-dish; or that Frank Elmore filched his success from Robson's experimental machine, which I repeat he never saw.

To understand some of the statements in Mr. Crowder's letter, and to refute your hasty conclusion therefrom, it is necessary to give certain facts. It is open to you as controlling a printing-press, to say with the celebrated detective, "I prefer my deductions to your facts;" but in your past kaleidoscopic presentation from time to time of the broken fragments of flotation history, you have at least shown your readers all the bits you happened to come across, so I ask you to add the following:

When my father purchased the Glasdir mine in 1896 he did so in association with a Mr. Hurst, an engineer of mining experience which was not then in the line of any members of my family; so the early operations and equipment of the property naturally depended on Mr. Hurst's judgment. The letters of Mr. Crowder senior show clearly that he failed to interest either my father or myself in his past oil experiments and he was requested to remove his small experimental machine, while steps were at once taken to erect concentration machinery.

The small experimental Robson mixer, with pump for driving oil through the thickened mass, was, while the mine was in our possession, never run; and although it was seen by me, it was quite ignored after possession of the property was taken, and it and its accessories had disappeared entirely before my brother, Frank Elmore, went to the mine as described in my previous communications. My brother had been fully occupied in certain electro-metallurgical works until he went to the Glasdir mine to examine the operation of the concentration plant more particularly. It is simply ridiculous to build up any argument from the circumstances to the effect that Frank Elmore obtained any help from the work of Robson, and that such help he and I have "disingenuously" denied. In the discussion of Rolker's paper before the Institution of Mining & Metallurgy in 1900 (after we had learnt something of history and practice in the use of oil) I gave Robson full credit for his prior work, and in my historical note, that same prior work is correctly set out; but as far as Frank Elmore in 1898 is concerned, the manner of his starting to experiment, and the results of his work, are precisely as set forth in my explanation in your issue of November 18, 1916, on page 726, ending with the words "as a matter of fact Frank Elmore has not at any time ever seen a Robson & Crowder machine." Even if he had seen the experimental machine, it would not alter the fact that he was induced to start on oil himself by the special observation referred to in my historical note; while the only important fact remains that his experiments, however started, led him in a diametrically opposite direction to Robson, and in consequence, to the development of the first practical working process.

It is inexcusable today for you to write "Mr. Crowder's letter of 1901 * * * affords a pathetic commentary on Mr. Stanley Elmore's insistent claim for originality in the use of oil for concentration by his brother and himself." My historical note is itself sufficient condemnation of such a mis-statement. There has been full publicity given to the earlier work of Carrie Everson and others and I personally arranged a pretty extensive distribution of the article by Walter McDermott in the *Engineering & Mining Journal* of New York on February 14 and February 21, 1903, beginning with the following words:

"The selective action of oil and grease on certain minerals has been made known by a number of independent investigators for some years, and several attempts have been made to utilize this knowledge for the purpose of a commercial separation of valuable products."

After describing the "greased tables" used for catching diamonds at the De Beers mine, the article continues:

"The attempt to use a thin oil for separating metallic sulphides from waste rock was made in England; and a certain measure of success was attained, in small experiments by causing the oil to pass through a moistened mass of ore. It was found that the oil used had very little supporting power; that it attached itself to the gangue to such an extent as to cause excessive loss; and the details of an effective separation of the sulphides from the supporting oil were not worked out."

Then the article proceeds to describe Frank Elmore's work.

In the case of the litigation between the Ore Concentration Co. and the Minerals Separation Syndicate, the grounds of our action were not that my brother and I were the inventors of the use of oil in concentration, but that the three men who formed the syndicate had with their engineers, worked in our testing-mill for nearly a year under a written legal obligation not to compete in any oil-concentration process; and that their various patents later acquired or taken out, were anticipated by us both by patents and by work done in the testing-mill.

Your broad conclusion that given the flotative effect of oil, results today are only due to skilful manipulation, would apply to all new processes, and all patentable improvements which rest on industrial application of given natural laws. As a philosophical summary by omniscient journalism it can be gratefully accepted, and it gives me that feeling of envy expressed by a famous statesman to a very cocksure individual: "If I could only be as sure of any one thing as you are of everything, I should be happy."

I may say in conclusion that you are in error in referring to my father as "the late William Elmore." Your suggestion of his death is like some of your other statements "grossly exaggerated."

A. STANLEY ELMORE.

London, April 11.

[We are glad to give Mr. Elmore space for his rejoinder. The cocksure individual to whom he refers was Thomas Babington Macaulay.—EDITOR.]

Grinding Plants Yielding Essential Oils for Flotation

The Editor:

Sir—For more than a year I have been endeavoring to solve the problem of economically separating galena from barite and fluorspar. The property producing the ore tested is about 35 miles from the railroad, and while water is plentiful the attitude of the owners of water rights was such as to limit efforts to handle a large tonnage. To this end experiments were made on dry-crushing and screening, and then hand-jigging (wet) after the manner of the Missouri lead-pocket miners. The tailing proved sufficiently high to warrant further investigation and flotation was tried. A small cell, modelled along the lines of the Callow type, was built. The sides were made of glass for the purpose of studying the action of the air, ore, and other minerals. Power was obtained by harnessing up the rear wheel of a Ford auto and air was supplied by attaching and adjusting the small power-pump used for inflating the auto-tires. A variety of oils was tried. With this rough outfit a saving was effected of 80 to 94% of the lead-content of an ore that averaged 10%. The scheme suggested a small plant that could be carried in an auto and used for prospecting. The plan is feasible and such a plant capable of handling about 300 to 400 lb. of ore per hour can conveniently be placed on an ordinary Ford car.

Independently of this rather comic mill on wheels, investigations were made on the utilization of desert-plant life as a means of supplying oils for flotation. Later an inquiry was addressed to the U. S. Bureau of Mines and D. A. Lyon, metallurgist, wrote, "we have tested samples of oils furnished by Maxwell Adams, of the University of Nevada. As a result we found that sage-brush oil gave splendid results. A small amount, less than $\frac{1}{2}$ lb. per ton of ore, gave clean concentrate and good extraction, when used with different kinds of ores. It proved especially good on the flotation of carbonates of copper which had received a film of sulphide by reaction with soluble sulphides. * * * Prof. Adams did not inform us as to how expensive a device would be required for the extraction of these oils from desert brush; however, we are of the opinion that such extraction will require considerable apparatus, as the oil used was refined and not the crude product which would be obtained by simple distillation of the wood." It then occurred to me that in the utilization of desert-plants and brush for flotation the plants could be ground and macerated with the ore, either wet or dry. Not having the facilities, these experiments have proved rather difficult. A limited number of experiments with fresh sage-brush, grease-wood, and other plants, have shown that the plan is workable, but certain elements enter into such a scheme to make the results uncertain. These crude experiments, nevertheless, may offer a valuable suggestion and may possibly inspire someone else to conduct experiments along this line.

Mining: The Great Adventure

By T. A. RICKARD

*In the book of Job it is written: "Surely there is a vein for the silver and a place for the gold where they fine it." The miner, in a cynical mood, has been heard to misquote these words of the old Hebrew poet and say: "There is a place for silver, and gold is where you find it." The word 'fine' in the Bible means 'refine,' of course, and, therefore, to say that there is gold where it is refined is like telling the prospector that the precious metal of his search is to be found at the mint. But the patient Job was not a man likely to trespass upon the patience of his fellows: the Revised Version puts a comma after gold and says, "which they refine." So the miner's saying, which most of us have often heard, is without biblical warrant. Yet I venture to tell a story of a later day in which the same idea found humorous expression. In November 1851, soon after gold had been discovered at Ballarat, in Australia, Charles J. Latrobe, the Lieutenant-Governor of the young colony of Victoria, rode to the diggings, then the scene of feverish activity. Passing along the flat at Golden Point he watched the miners at work and talked with them. Finding himself chatting with a man of more than average intelligence, he put forth the great conundrum: "Where do you think the gold came from?" The old Cornishman—of course, he was a Cornishman—leant on his shovel, scratched his head for a moment, and then answered: "Well, sorr, wheer it is, theer it is; and wheer it ain't, theer be I." That reply remains to this day the epitome of geologic vision and mining realization. Nevertheless the diggings at Ballarat furnished the setting for one of the world's biggest adventures. What a 'rush' that was! Sailors deserted their ships, clerks jumped off their stools, traders abandoned their counting-houses, every able-bodied man shouldered his blanket and made tracks for the gold mines. The news reached Europe and started a stampede. Ships came crowded with people so unsophisticated in mining that they thought gold in quartz meant that the metal was to be found by the double-pint. They had much to learn, like most of us, and they were taught, as most of us are, by that supremely wise and forceful teacher, the professor whose name is Experience. It was a great hegira. From the mining camps eager prospectors plunged into the 'bush,' the forest primeval that covered the habitable portions of Australia. They found more golden gravel and they discovered also the grassy uplands on which the Australian was to grow a later silver fleece, a source of wealth more abundant than the gold, and more beneficent.

This hint of the golden fleece recalls the adventure of

an ancient day. According to the classic myth, Jason and his comrades sailed on the ship Argo from Thessaly, on the quest of the fabled Golden Fleece, which was in Colchis. The king of that country consented to yield the precious fleece if Jason would perform sundry prodigies, which would have been beyond his strength if Medea, the king's daughter, a typical wise woman, or witch, had not given him a charm that helped him in his hour of trial. By aid of this he won the prize. He seized the fleece and fled home with his sweetheart and friends.

The fable may be interpreted thus: The sacred ram, the fleece of which Jason sought, refers to the Tibareni, or sons of Tubal, whose name means 'hammer,' for Tubal was a smith—the first of a noble and numerous family. The Tibareni were a tribe that mined for gold near the northern shore of Asia Minor. They washed the gravel of the gold-bearing stream into sluice-boxes on the bottoms of which they placed sheep-skins to arrest the fine gold. When the time came to clean-up, they removed the sheep-skins, shook out the coarser particles of metal, and hung the fleece to dry, so that the fine gold might be beaten out of it and saved. Thus the Greek mariners heard of the land in which golden fleeces hung on trees in a sacred grove by the Euxine. Jason is the type of youth, the seeker who goes forth with his comrades across the sea on the miner's quest. He finds that he must perform prodigies of labor before he can win the precious metal. In winning it he is aided by the sorceress Science, the modern Medea, who shows him how to use the fleece for arresting the fine gold in the bed of the stream Colchis, and even explains to him that the natural grease on the wool serves to promote the adhesion of the particles of gold. Placer mining, the aid of science to industry, and even flotation, are typified in the story of the Argonauts.

We recognize the undying truth of the ancient myth and speak of the Golden Age in California, of the Argonauts of '49, and of the Eldorado that they found in the foothills of the Sierra. Thus we mingle two tales, that of Colchis, and that of a fabled land called Eldorado, which, however, referred originally not to a country but to a person—*el dorado*, the gilded one, or *el hombre dorado*, the gilded man. In the spacious times of Queen Elizabeth, the sailors and buccaneers that sailed for the Spanish main were lured by the tale of Eldorado. Raleigh and his men, like Pizarro and his followers, heard the story so often that it seemed to become true by much telling. Juan de Ampues in 1527 found the tradition full-fledged among the Coquetios Indians in Venezuela. According to them, there dwelt a fierce tribe in the southern mountains where gold was so abundant that the Indians powdered the whole body of their chief

*An address delivered on the occasion of Commencement at the Colorado School of Mines, May 25, 1917.

with the dust. This tale of the gilded cacique became the will o' the wisp of mineral exploration, the something beyond the range that enticed the prospector of a romantic epoch across the swamps, into the jungle, and over the snowfields of the Andes into those mysterious forests that cloak the interior northern parts of South America.

One of the later versions of this myth referred to the Chibchas, a semi-civilized race dominating the plateau of Santa Fé de Bogotá, in Colombia; their chieftain, on the occasion of a high festival, would strip himself and be anointed by the priests with mud from a sacred lake; they would then blow gold-dust upon him, gilding him from head to foot, in which guise he would perform the religious ceremony in honor of the Sun. Thus Colombia shared with Venezuela the honor of being the cradle of this legend, which, furthermore, declared that there existed a great interior sea, in the centre of which there was an island, upon which stood the city of Manoa, where gold was so abundant that the roofs were made of it and the streets were paved with it. Exploration drove this lake out of Colombia and then out of Venezuela; it retreated into the vague hinterland where the Rio Negro and the Orinoco have their source, but so persistent was the belief in the story that all maps of South America, from the first attempts at accurate cartography by Padre Fritz in 1616, down to the school-maps published as late as 1840, in the United States, showed this lake with its city of Manoa. Slowly the lake shrank on the maps and its position shifted uneasily until it became hidden in the last unexplored portion of the Amazon valley, the territory of the Roucouyennes, at the foot of the Tumac-Humac mountains, in Brazilian Guiana. Finally, about 35 years ago, Jules Crevaux, an intrepid French explorer, followed the legend to its last abiding place. He found that the chief village of the Roucouyennes was on a slightly elevated plateau in this low-lying region, and on the plateau there dwelt a tribe of Indians of great stature and of light color. He ascertained, by residing among them for two years, that they held an annual festival at which the chief was anointed with oil, after which he was dusted with mica from the schist of the Tumac-Humac mountains. This chief, being oiled, was covered with the yellow spangles of mica, the 'near-gold,' 'tender-foot' gold, or 'new-chum' gold, of the unsophisticated. And so the bubble was pricked—another suggestion of flotation. According to the technology of today the oil ought to have enabled the bubble to survive—but perhaps that idea too will prove to be a myth before many years are gone.

Thirty years ago, losing my way among the foot-hills of the Sierra Nevada, I stumbled upon a deserted mining camp—half a dozen bedraggled shanties, abandoned prospect-holes, deserted save for a couple of wretched Chinese coolies. The name of this derelict of mining was Eldorado. The word threw a halo of romance around those empty cabins in the silent pine-woods. No 'deserted village' of poetry was this, yet even 'Sweet Auburn' suggested sentiment less poignant: from El-

dorado to empty shacks, from extravagant expectation to bitter disillusion.

South America had its gilded man, but California had its golden age. What a colossal adventure that was! It involved so much more than mines, and John A. Sutter was the central figure of the story. A Swiss, at the age of 31 he came to New York and migrated to Missouri, where he heard enough about California to want to go thither. He achieved his purpose in a roundabout fashion; proceeding in 1838 across-country to Vancouver, thence to the Sandwich islands, where he found no vessel going the way he wanted, so he sailed to Sitka, in Russian Alaska, and from there, at length in 1839, reached Yerba Buena, the little settlement that is now San Francisco. Accompanied by the eight Kanakas that he had brought with him, he sailed up the Sacramento river and established himself at New Helvetia, now Sacramento, where he erected the stockade that became known as Sutter's Fort. At that time the Mexican ruled California, but the Russian also had a foot-hold. Fort Ross and Russian river, in Sonoma county, are names that but vaguely recall an incident that might have had quite another meaning. It was there in 1812 that a Russian farming settlement was established by an expedition, under Alexander Kuskoff, from Sitka. This Russian post was due to the far-seeing design of that Nicolai Rezanoff whose romance with Concepción Arguello, the commandante's daughter at the Spanish fort on San Francisco bay, is preserved in Bret Harte's verse. Rezanoff won her love, he was recalled to Russia, expecting to return, but he died by an accident on the way and with him perished not only a dream of empire but the happiness of a woman.

"So each year the seasons shifted—wet and warm and drear
and dry;

Half a year of clouds and flowers—half a year of dust and sky;

Yet she heard the varying message, voiceless to all ears beside;
'He will come,' the flowers whispered; 'Come no more,' the dry
hills sighed.

Still she found him with the waters lifted by the morning
breeze—

Still she lost him with the folding of the great white-tented
seas."

The Russian colony in Sonoma did not prosper. In 1839 it was offered for sale to the Hudson's Bay Company, and in 1840 to the Mexican government of California, but it found no purchaser. Thereupon Sutter, whose fortune was in the ascendant, appeared on the scene, and on December 13, 1841, he bought the entire property, with its cattle and improvements, for \$30,000. The Russian garrison embarked in February 1842. That ended the Russian occupation in California. Sutter sped the parting Russians with his left hand and welcomed the arriving Americans with his right. His ranch on the Sacramento river stood in the track of the pioneer bands that were beginning to cross the Sierra Nevada into the great valley of California. Although he had become naturalized a Mexican, he disregarded the Governor's polite request to oppose the invasion of new-

comers from the United States; instead, he gave them the 'glad hand,' foreseeing that they were likely to become the masters of the country. That was five years before the discovery of gold. He organized a military company and played a half-hearted part in the revolutionary troubles of Alta California, as this Mexican province was called. When Mexico and the United States went to war he raised the American flag over his stockade on July 8, 1845. He served as Indian agent for the American administration and proved himself a good citizen in many ways. But his great opportunity was yet to come. A shrewd man, he saw that the influx of settlers would create a demand for lumber; so he started to build a saw-mill. He engaged James W. Marshall, a carpenter from New Jersey, to build the saw-mill at a place called Coloma on the south fork of the American river. How these names—Marshall, Coloma, American river—vibrate with romance! You know the story of the gold discovery, yet I dare to repeat it.

When the saw-mill had been built, Marshall found that the tail-race was not deep enough, so he scoured it by opening the water-gate to full capacity. The water ran all night, and in the morning he closed the gate while he examined the mill-race to see if it had been sufficiently deepened. In the gravel loosened by the current he saw several bits of yellow stuff. He took one of the nuggets and hammered it, proving that it was metallic; he bit it and found that it was soft; he put it into the soap-kettle of Mrs. Weimer, who was cook for the mill-hands, and it emerged bright but insoluble. Thereupon he decided that it must be gold. At once he went to New Helvetia, 53 miles distant, to tell Sutter about the discovery. Locking the door of Sutter's office, he pulled out a rag in which the nuggets were wrapped. Sutter applied the acid test, having some nitric acid among his apothecary stores; he read the article on 'Gold' in his copy of the *Encyclopedia Americana*; he weighed the specimens and compared them with gold coins; whereupon he pronounced it 23-carat gold. And his dictum spoken in that frontier store went out to all the world; at first a whisper, then a mighty shout, it called the adventurous of every land to California.

But Marshall did not profit from it, nor did Sutter. His laborers left the saw-mill, his staff at the ranch decamped for the diggings. The mill was deserted and even the mill-stones were stolen; his tannery went to ruin; even the Indians refused to harvest his crops; the miners stole his cattle and rode off on his horses; prosperous before, Sutter was beggared by the gold-seekers and by the conditions they created. Nothing remained but for him also to search for gold. He organized a prospecting expedition, but it was a failure, and, in the end, he had to be pensioned by the State of California. Marshall also received some little help from the State, but he died a poor disappointed man. In 1851 California yielded \$81,294,700 in gold. The date of the discovery was January 24, 1848, and the treaty of Guadalupe Hidalgo, ending the first Mexican war, was signed on February 2; in other words, California was ceded to the United States nine

days after the fateful discovery, no whisper of which had reached either of the signatory governments. Sutter and Marshall kept the news from spreading as long as they could. What would have happened if Marshall's find had been made one year earlier? Would Mexico have yielded so rich a mineral domain, which included Nevada, Utah, Arizona, and part of Colorado also, for \$8,250,000, even at the point of the sword? Would Russia and England have acquiesced in the cession so unconcernedly? It was a wonderful coincidence—as remarkable as the fog that prevented Drake from discovering the Bay of San Francisco in 1578. We may well be grateful for the fact that the discovery of gold did not come to create a bone of bitter contention but to stimulate the founding of a great commonwealth.

Soon the wilderness west of the Missouri river was threaded by long trains of wagons bearing the gold-seekers to California. So eager were they to reach the new Colchis on the Pacific Coast that they had no time to examine the signs of mineral wealth strewn on the barren ridges rising above the dreary desolation over which they trekked. Many of them entered California by the trail that followed the Carson river to the crest of the Sierra, south of Lake Tahoe, and then descended among the pinewoods of Placerville, where they went to work with pan and shovel in the gold-bearing streams tributary to the American river. The Carson valley became a resting-place on the road. It was an oasis in the desert pilgrimage. That migration was like the march of an army of camp-followers; it included all sorts and conditions of men and women, even children. Among others a party of Mormons came westward from Salt Lake City in 1849, and one of them, William Prouse, of Cornish origin, panned gold in a little creek that entered the Carson river from the west, where the town of Dayton now stands. The gravel was not rich enough to beguile the prospector from the larger lure that lay across the mountain rampart separating from California what was then part of Utah, but is now Nevada. That little creek became known as Gold Cañon; it was the door to one of the treasure-vaults of the world—the Comstock lode. After the Mormons had passed, a group of Mexicans, from Alamos, in Sonora, tried to work the gravel with their bateas, separating the gold from the debris by 'dry-washing,' using air instead of water as the medium for their concentrating process. But their winnings were small and supplies of every kind were so costly that no ordinary yield would suffice. So they also quit. Others came, for the diggings were near the overland trail. A little camp was established in Gold Cañon in 1851. Long-toms and rockers became numerous, and the placer miners slowly worked up the creek toward the great vein from which most of the gold had come. About \$100,000 worth of gold was extracted annually until 1857, by which time the gravel in the lower part of the creek and on the bars of the Carson river had been pretty well worked out.

We may feel surprise that the indications of greater riches in the outcrop that crossed the ravine near its head were ignored so long, but we who have read last

year's almanac and can view the signs of ore in the light of later knowledge must make allowance for the complete ignorance of vein-structure and ore-distribution prevailing among those early prospectors. Besides, the miners that were content to make a few dollars a day in Gold Cañon were a shiftless, ignorant, sodden lot. Not all of them; among the illiterate mob that found slim pickings in the gulch were two brothers named Grosh, the sons of a clergyman in Pennsylvania. They came to Gold Cañon from the Californian side, having had some experience in Eldorado county. They were intelligent and observant young men, and they went up the gulch to find the source of the gold. In 1856 they wrote to their father telling him that they had found silver, "it resembles thin sheet-lead broken very fine, and lead the miners suppose it to be." The placer miners had often complained of the heavy mineral, called by them 'sand of iron' and 'blue stuff,' that clung to the bottoms of their sluice-boxes and clogged their rockers. They had no idea that it was hornsilver and argentite. Later the Grosh brothers reported the finding of "two veins of silver at the forks of Gold Cañon . . . one of these veins is a perfect monster." This was the outcrop of the Comstock lode. Their first assay of the 'black rock' showed \$3500 per ton in silver. A reference to cupellation suggests that they had a portable muffle-furnace. Thus they prospected for silver when not earning a bare living by washing for gold in the gulch. Their hands had touched the Great Bonanza, but they did not know it and they did not live to profit from it. Tragedy dogged their footsteps. First their backer, George Brown, a cattle-trader in the Carson valley, was murdered. Then one of the brothers, Hosea Grosh, died from the effects of an accident to his foot. Finally, the other brother, Allen, died from exposure while crossing the range into California during the winter of 1857. His papers were thrown away when he and his companion, Richard Bucke, were struggling in the snow. Bucke barely survived, and after regaining some measure of strength betook himself on bandaged stumps to Canada. So the heavy hand of misfortune erased the exploratory work of these intelligent young men, and it was left for a drunken loafer and a shifty imposter to give their names to Virginia City and the Comstock Lode. The heirs of the Grosh brothers later engaged in long and costly litigation in an effort to enforce their claims, but without success.

James Finney, a native of Virginia, known therefore as 'Ole Virginny,' a prospector during sober intervals, was rambling along the hillside above Gold Cañon when he espied an outcrop of quartz. Thinking it might denote a vein, he wrote a location notice on a slip of paper, which he hid among the loose stones. This was on February 22, 1858. He did not record his claim, he made no attempt to work it, and it proved of no consequence except as the excuse for an unsuccessful lawsuit. Subsequently he noticed a mound about a mile south of his location and early in 1859 he and some others panned some crumbly earth that they found at a gopher-hole on the edge of the mound. It was so rich in gold that they staked

four claims of 50 ft. each. This mound was part of the outcrop of the big lode and became known as Gold Hill; it was a veritable golden hill, for it all passed through the mill in the course of a few years, and in its place was a big 'glory-hole.' Meanwhile other placer-miners working up a gulch to the north, at the head of Six Mile canyon, had moved so far from the creek-beds that two of them, Patrick McLaughlin and Peter O'Riley, were no longer washing alluvial ground, but the debris of erosion. This was at the mouth of Spanish Ravine, more than a mile north of Gold Hill, but they also were working just below the outcrop of the great vein, which extends north and south for several miles. McLaughlin and O'Riley were not doing well at all, the surface did not yield much gold, and they had only a trickle of water, which they had to conserve carefully. On the 8th of June, 1859, while digging a water-hole, they noticed that the earth contained yellowish sand, bits of quartz, and pieces of black rock. This was material of an unfamiliar kind. However, they had to try it, so they washed a little of it in their rocker and were astounded to see the gold that was left on the bottom. They tried some more of it, with a similar result. The metal was of a pale color—on account of the silver alloyed with the gold—but still it looked good enough. They were overjoyed. Just then a lank fellow on a small horse came riding toward them. It was Henry Comstock, formerly a fur-trader and trapper in the North, a talkative trickster. He caught sight of the gold and saw that something rich had been uncovered. Dismounting, he fingered the gold and asked some questions. Coolly he informed the two Irishmen, who had staked two claims, that they were trespassing on his property. He asserted that he had a ranch of 160 acres covering the ground, which included the water-hole and the trench in which the prospectors were at work. It was all bluff—a rank imposture—but he talked so loudly and so confidently that McLaughlin and O'Riley thought it best to pacify him by acceding to his demand, which was that he and his partner Penrod were to be given an equal share in the discovery-claim. It is a remarkable coincidence that the placer miners in Gold Cañon and those in Spanish Ravine should have, independently, worked up to and discovered the great lode at about the same time. Meanwhile, a meeting of miners had been called to frame regulations for a new mining district, so, in order to obtain an undisputed right to their claims, Comstock and his three partners concealed the discovery by filling the hole and obliterating other traces of their work. The meeting was held on June 11; next day Comstock and his partners, over whom he had easily asserted loud-mouthed leadership, located 300 ft. for each man and an additional 300 ft. for the discoverers, making 1500 ft. in all along the lode. At the southern end of the lode, at Gold Hill, the miners took up much smaller claims, being governed, apparently, by the custom regulating placer locations. The summer of 1859, until the Nevada City quartz-miners arrived on the scene, was spent in feverishly washing the rich earth in the small gulches along the lode. These ignorant placer-

miners did not realize that they had uncovered a great vein. The pieces of black rock and dull metal were thrown aside. At a depth of four feet, McLaughlin and O'Riley cut into a seam of black stuff several inches thick, but it was regarded as a nuisance only. The loose earth became clotted with the soft yellow sand, so that it could be washed no longer in a rocker. Thereupon two arrastres were procured. For these two arrastres, and the two horses required to operate them, the claim-holders traded two-sixths of their property. By aid of these Mexican milling-machines they began to make money fast, for the grinding-stones crushed the yellow sand, which was silver chloride, so that it amalgamated readily. The black rock or 'blue stuff,' as they called it, was still neglected. Its value did not become known until several specimens of it were carried by a farmer from Truckee and by him given to two competent assayers at Nevada City. At last the ore had passed into the hands of capable investigators. They assayed it and found that it was worth \$1595 in gold and \$4791 in silver per ton. The mineral was argentite containing native gold. That night two capable miners, Judge Walsh and Joe Woodworth, loaded a pack-mule and started on horseback for the discovery, and within a few days hundreds of men followed them. The 'Washoe rush' had begun. Walsh and Woodworth got there first and bought out Comstock and his partners for a few thousand dollars. The original prospect-hole of McLaughlin and O'Riley became the Ophir mine, which has yielded \$17,655,000; the stopes of this mine grew so unmanagably large that the square-set system was devised by Philip Deidesheimer to keep them open. If the true discoverers, the Grosh brothers, failed to achieve success, it is also a melancholy fact that the other actors in the drama profited but little from the Great Bonanza. Comstock died miserably, by his own hand, in 1870, and both of those whom he partly dispossessed died paupers and without honor.

The discovery of the Comstock was almost as fortuitous as the finding of a purse in the street by a drunken sailor. The placer-miners knew little about vein-mining and nothing about silver-mining. The mining of silver was unknown in the United States previous to the discovery of the Comstock and the knowledge of minerals, as also knowledge in general, was lacking in the cabins of Gold Cañon. But the opening of the great treasure on the lower slopes of Mount Davidson brought to the Comstock all the sciences that were needed to guide skilful exploitation. The figures of production are staggering. The entire output of gold and silver exceeds \$500,000,000. In the early years, the value of the gold in the ore exceeded that of the silver. Of the total production of the mines, about 56% of the value was silver and 44% was gold. The losses made in milling and the money stolen are not recorded, but they form part of the yield of the great lode. By 1867 the shallow orebodies were exhausted, and the future looked dark. Then, in 1870, the Crown Point found its famous ore-shoot at a depth of 1100 ft. and the Comstock took a new lease of life. In 1873 the Consolidated Virginia Mining Company, gen-

erally known as the 'Con. Virginia,' found the top of its ore-shoot at a depth of 1100 ft. from the surface. This orebody extended into the California; it yielded \$131,759,399 in metals and \$78,148,800 in dividends up to the end of 1899. Nearly all of this was produced in five years, from 1874 to 1879, during which 1,000,000 tons was mined that averaged about \$100 per ton. For three years, after the big orebodies were uncovered between the 1100 and 1600-ft. levels, the Con. Virginia and the California produced \$3,000,000 per month, and dividends at the rate of \$1,080,000 per month were paid by each mine. This enormous production incited an orgy of stock-gambling in all the mines along the Comstock lode, good and bad. There were only a few richly productive mines, a few more that found ore but paid no dividends, and a flock of others that never paid anything but 'Irish dividends,' that is, did nothing but collect assessments year in and year out for a generation or more. The stock-gambling excitement, however, kept these alive. The discovery of ore in any one mine greatly affected the value of all stocks, and the fluctuations of the market were almost incredible. Mines sold for millions that never had a pound of ore. Wallingford might have taken lessons from some of those early Comstock manipulators.

In 1871 the mining properties that became merged into the Con. Virginia and the California had a market-value of less than \$50,000. In 1875 the shares of these two mines were valued at over \$160,000,000. An earlier instance of a remarkable rise in stock was that of the Crown Point, the shares of which rose from \$2 to \$1825 in less than a year. In these two instances, however, the discoveries were of such size and richness as to justify the market. In 1875 Philip Deidesheimer estimated that the Con. Virginia bonanza would produce \$1,500,000,000 and he and his friends went bankrupt on that appraisement. Within eight months, in 1878, the shares of the Sierra Nevada mine rose from 50 cents to \$275 per share, but this rise was based on nothing but market manipulation. One thousand dollars was sometimes turned into half a million in less than a year. Money was made easily and lost recklessly. The Comstock became a byword for tricky dealing, extravagant management, and fickle fortune. It had a wonderfully fascinating history, however, and its gold and silver enabled the battle-born State of Nevada to enrich the Nation in an hour of need—the Civil War.

The gold and silver have been spent, but there remains much that time cannot destroy. The art of mining was developed by the men that pierced deeply into the roots of Mount Davidson; some of those who won wealth at the point of the pick took their places among the Napoleons of finance; others became captains of industry. Mark Twain has peopled Virginia City with characters that will live when the underground galleries are sealed by the healing processes of nature. I visited Virginia City a few years ago and stood on the ground where geologic agencies had accumulated a treasure beyond a pirate's dream.

"Cold upon the dead volcano
Sleeps the gleam of dying day."

The sunlight fell on abandoned shaft-houses, the rain had rusted the motionless machinery, and far below was the canyon where the first diggers delved and died. The stream survives their interfering labors and now the Chinaman uses it more productively than the miner.

"The river still is winding, still is winding,
Past the gardens where the Mongol tends the cabbage and
the leek."

Another fabulous source of gold was Ophir, whence Solomon is said to have obtained his wealth; although he probably acquired most of it by reason of the fact that Jerusalem was on the great caravan route between the Nile and the Euphrates. At various times every ancient digging near the Red Sea or the Indian Ocean has been put forward as a claimant for the honor, from Nubia to Kolar, from Abyssinia to the Mountains of the Moon. Dr. Carl Peters thought he had found it at Fura, a corruption of the word Ophir adopted by the Portuguese from the Arab traders; hence 'the gold of Arabia.' Fura is in the Zambesi region. Even the word Africa has been traced by an etymological twist from Ophir, through Afir, Afer, and Africus. Wherever Ophir was, the output of gold must have been stupendous, according to biblical statistics. In First Chronicles XXIX, 4, it is written that King David contributed to the building of the temple "three thousand talents of gold, of the gold of Ophir." A talent is equal to 114 pounds troy, so that the 3000 talents represented over \$80,000,000 of our money. In the same context it is written that the fathers and princes of Israel contributed 5000 talents and 10,000 drachms of gold "for the service of the house of God." That means \$135,000,000 more. There were great stores of gold in Egypt and the Euphrates valley and throughout Asia Minor long before the times of David and his son Solomon, and it was undoubtedly derived in large part from placer mines. Herodotus speaks of gold being so common in Ethiopia (Abyssinia) that they used chains of it to fetter slaves. Copper was the precious metal because of its scarcity. In recent years the mighty ruins of Zimbabwe, in Rhodesia, were identified as Ophir, until an unromantic archeologist spoiled the fancy. Wherever it was, we know that the quest of Solomon's mines stimulated prospecting in the heart of Africa and opened the dark continent to modern industry. Among other adventures due to this search I may relate that of the expedition to Mashonaland, a company of 187 courageous and energetic men, organized by Cecil Rhodes in 1899 to penetrate the region north of the Transvaal and west of Portuguese East Africa. The country of the Mashonas had been identified as the place of Ophir and King Solomon's mines by a German explorer, called Mauch, who spread tales of a hidden Eldorado among the Boer vortrekkers. The expedition sent by Rhodes was commanded by Major Frank Johnson, now a chairman of mining companies in London; it was guided by F. C. Selous, the celebrated big-game hunter of Africa. This company of men, called the Pioneers of Mashonaland, set

out to explore the region, to make a road, and to commence mining. Their safety depended upon the word of Lobengula, the chief of the warlike Matabele, who had given Rhodes a concession. "There is a wall built round the word of a chief," the old warrior said, and he proved it. The expedition was subject to attack from other quarters, not to mention malaria, and the venture was hazardous. It was a big grubstake on the part of Rhodes and his British South Africa Company, which he had organized for exploratory expansion in what he was fond of calling the 'hinterland.' The men that set out on this trek were a fine lot: soldiers, athletes, hunters, miners, frontiersmen of the best kind. At Tuli they crossed the northern border of the Transvaal and there began to clear a road through the bush as they advanced. As the trees were cut down the heavy ox-wagons made ruts that defined the road and extended the trail of empire into the wilderness. Selous led the way. He was then 40 years old; 20 years earlier he had stood before Lobengula and asked permission to hunt elephants and lions. The old warrior laughed, but gave the permission. When the news of the boy's exploits reached the great chief he swore a mighty oath and proclaimed the young Englishman the greatest of all hunters. The Pioneers loved him. He was a fine figure of a man, deep-chested yet nimble—the Allan Quatermain of Haggard's story. His voice was well modulated and his eyes a clear blue. "A mighty hunter before the Lord" was he, fearing neither man nor beast. Twenty-five years later, in 1915, when 64 years old, he obtained a commission and joined the British forces that were fighting the Germans in East Africa. In September 1916 he was promoted to captain and awarded the D. S. O. "for conspicuous gallantry, resource, and endurance." In January of this year he fell while leading his men in battle. He was shot and mortally wounded, but continued to urge his men forward until he was hit a second time, fatally. When the news of his death reached New York, another fearless man and mighty hunter, Theodore Roosevelt, said: "It was a fit and gallant end to a gallant and useful life." A son of Selous is now serving in France. Let us claim him as one of the heroic band of prospectors that have opened the waste places of the earth to human enterprise.

On September 12, 1890, the Pioneers of Mashonaland completed their trek of 430 miles and founded Salisbury, taking possession of the country in the name of the British South Africa Company. Having finished the first portion of their task, they grouped themselves into little syndicates and prepared to seek for gold. Each syndicate had a wagon and a span of oxen, rations for three months, tools, dynamite, and other supplies, besides goods for trading with the natives. The expedition had been followed by a number of prospectors, who now scattered over the surrounding region. It was the expectation of Rhodes and his associates that lodes richer than those of the Rand would be found and that in a short time the discoveries of gold would attract a large population. This hope proved fallacious. Gold was found in the Hartley hills, Gatooma, Lomagundi, and other districts,

and eventually a number of productive mines were developed, but the mining industry never grew to lordly proportions. Many of the mines were founded on ancient workings, usually about 50 feet deep, dug by a forgotten people. However, if the immediate results seemed unimportant the ultimate consequences proved far-reaching. This band of pioneers prepared a way for others, they started the mineral exploration that opened the interior of South Africa to orderly development, they broke the ground for peaceful agriculture and civilized habitation from the Cape of Good Hope to the sources of the Nile.

One more story: that of the three lucky Swedes, as they became known in the North. John Brynteson was a Swede who had worked in the iron mines of Michigan. Erik Lindblom, another Swede, was a tailor in San Francisco when the lure of gold called him from the bench to Alaska. Jafet Lindeberg, a Norwegian, came to Alaska in charge of the herd of reindeer that the United States government brought over from Lapland. These three men chanced to meet at Council, on the Seward peninsula, in August 1898. Lindblom was 44 years of age, Brynteson 28, and Lindeberg only 22. They formed what Lindeberg called "a prospecting companionship," a little company of honorable adventurers in search of the Golden Fleece. They were energetic and intelligent fellows. While prospecting roundabout Council they studied the methods of placer-mining and took pains to learn the mining regulations; finding that all available ground in the district had been over-run by stampeders and staked to the mountain-tops, they decided to go elsewhere. Brynteson had been farther up the coast with some other prospectors just before he met Lindeberg and Lindblom, and he told them of the finding of gold in the creeks at the upper edge of the coastal plain. So they left Council and went down to Golovin bay, where they procured a boat and provisions. They set sail September 11, 1898, on a voyage that proved eventful. Proceeding along the coast they stopped at the mouths of the streams that flow into Bering Sea; they did some prospecting, but not finding enough gold, went farther west to where the Snake river meanders through the tundra to the sea. This became the site of Nome. It was about 100 miles from their starting point. Having been to Nome, I can picture the desolate landscape—then absolutely devoid of human touch—the chill gray waters lapping a long beach fringed by the moss-covered plain stretching to forbidding hills. They did not linger on the seashore, although the beach-sand showed some gold. They ascended the slow-flowing river in their boat as far as the mouth of a creek where Brynteson had panned gold on his former trip. Lindeberg was quick to infer that the gold on the shore must come from up-country, and determined to search for its source. They prospected several creeks the names of which now to an Alaskan are as eloquent of gold as Colchis or Pactolus to Macaulay's schoolboy. It is a remarkable fact that these three men, novices in alluvial mining, should have been able, after a hasty inspection, to select what later proved to be the richest portions of several creek-bottoms. They located a joint dis-

covery-claim on Anvil creek, and then each located a claim in his own name on this creek as well as on Snow, Glacier, and Rock creeks. They knew what they were about; they showed rare judgment in locating, and they took pains to comply with the law. All of these claims were subsequently consolidated under the name of the Pioneer Mining Company of Seattle, and Mr. Lindeberg became the president of the company. When the three prospectors returned to Council, in October, the news of the discovery soon spread, causing a rush. A party was organized by the three Scandinavians and three others, who went to the mouth of the Snake river and organized the Cape Nome mining district. The whole country was soon plastered with locations, most of them illegal. The prospectors that had done the first gold mining in this region, the Seward peninsula, were chagrined to find that the three Scandinavians, comparatively inexperienced as they were, had located the best claims; so they jumped the claims of Lindeberg and his partners on Anvil creek, and set an example that was followed at once by the crowd of newcomers. Every claim was covered two or three deep with locations. Anarchy ensued, culminating in a disgraceful litigation, rendered long and costly by a gigantic conspiracy on the part of the local authorities established at Nome. Never was the law worse prostituted by graft, and never did a man fight more courageously and fairly against big odds than Lindeberg on behalf of his 'prospecting companionship.' To the honor of American journalism be it said the *Washington Post* was instrumental in exposing the whole shameful story, causing the Senate to call for an investigation. The Federal court at San Francisco, notably Judge Morrow, checked the outrage and prevented the robbery from being consummated while investigation was being made. The judge at Nome was dismissed and a great wrong righted. Lindeberg came into his own, after a fight that had lasted three years. He proceeded to exploit the gold-bearing creek-bottoms in a miner-like way and organized a thoroughly efficient enterprise, which proved highly profitable. The Pioneer Mining Co. has produced \$17,000,000 in gold, of which \$6,000,000 has been distributed in dividends and \$4,000,000 spent in property and equipment. It is still productive. And when he had made money Mr. Lindeberg did not forget his native place, Tromsø, but furnished funds for building schools, giving to his younger countrymen some of the educational advantages that he had been compelled to acquire as best he could during the rough and tumble of his great adventure.

This is the story of a recent day. The heroes of it are living and working still. It is a pleasant story, because it tells of wrong righted and of intelligence rewarded. The ignorant and the envious among their fellows exclaimed at the "stupid luck" of the gallant three, but it is a fact that they prospected on every claim that they staked, they worked diligently, and they ascertained where lay the richest ground before their locations were made. They were wise also in studying the mining law before they started on their exploration, so that they

knew how to comply with it in every detail when the time for action arrived. They were strong men, as able to withstand the attack of unscrupulous foes as they were fit to face the hardships of a stern cold land. Such are the true sons of the North, not the dissolute weaklings or the unhappy misfits of a material civilization but the men with the heart of a viking and the faith of a child, to whom the call of adventure is as the voice that the caribou hears in the spring. Every young miner hears that call.

"Something hidden. Go and find it. Go and look behind the ranges—

Something lost behind the ranges. Lost and waiting for you. Go."

You will go, will you not? You will light your campfires in the solitary places and steer your boat amid uncharted seas. You will

"Whistle bits of rag-time at the end of all creation,
And learn to know the desert's little ways?"

"They have cradled you in custom, they have primed you
with their preaching,

They have soaked you in convention, through and through;
They have put you in a show-case; you're a credit to their
teaching—

But can't you hear the Wild? It's calling you."

Let us probe the silent places; let us seek what luck betide us;
Let us journey to a lonely land I know.

There's a whisper on the night-wind, there's a star agleam to
guide us,

And the Wild is calling, calling . . . let us go."

But I must not stop here. To you, today, comes a higher call, the call to serve your country even in the cannon's mouth. You are drawn by the romance of a greater adventure than any of which I have spoken, by the greatest of all adventures, that in which a man risks everything, not life alone, but his ambition and his career, in order to fight for the noblest of all causes, that of national honor and human freedom. The world cannot remain "half slave and half free." Representative government must not perish. Civilization shall not be mocked by deliberate wrong and bestial cruelty. It is for you to carry the flag of Washington and Lincoln to the forefront of the battle to ensure "life, liberty, and the pursuit of happiness" not only in this great land but wherever the human spirit breathes the hope of higher things. You will answer that call, you will play your part in that proud adventure, you will acquit yourselves like men, so that not this nation only but the whole world "shall have a new birth of freedom, and that government of the people, by the people, for the people, shall not perish from the earth."

Tin is dissolved by the acids present in fruits and vegetables. Even foods of relatively slight acidity will dissolve tin from the walls of the can, which is then adsorbed from the solution by the proteins and carbohydrates. It is not known whether this action is due to direct adsorption of the tin ions, or whether the tin-salt is first hydrolyzed and the resulting stannous hydroxide

then adsorbed; in either case the acid is regenerated and will dissolve more tin from the can, so that the contents finally become highly charged with the metallic product. Among the canned foods that dissolve the largest quantities of tin are black cherries, raspberries, squash, string beans, red cherries, pumpkin, strawberries, and tomatoes, in the order named, the percentage of the metal in the ash ranging from 83 down to 38%.

Volumetric Chromate Determination of Lead

By JOHN WADDELL

*The method described is most satisfactory in those cases in which the molybdate method is least reliable, namely, with ores poor in lead and containing a large amount of calcium carbonate. It was originally proposed and used by H. A. Guess, but the results were not as closely accordant as desirable, and the modifications herein given have overcome the difficulties, and have been fully tested.

The method as originally given by Guess in the Transactions of the American Institute of Mining Engineers was as follows:

"To the ore-charge of 1 to 5 grammes in a 250-c.c. flask add from 3 to 5 c.c. of strong nitric acid and 15 c.c. of strong hydrochloric acid; digest until everything is in solution and the excess of acid has been reduced to about 8 c.c. The whole operation on the hot-plate requires but 15 min. The flask is then removed, and moderately diluted ammonia is added slowly in slight excess, the neutralizing action being sufficiently vigorous to render the content of the flask quite hot. Acetic acid, of 80% strength, is then added slowly, the flask being shaken vigorously until the smell indicates a decided excess. Then add 5 c.c. of strong ammonium acetate to insure the solution of any lead compounds remaining undissolved by the ammonium acetate already formed in the flask. If the ore contain no antimony or separated gelatinous silica, and if the silicious residue in the bottom of the flask is only in slight amount (as is usual with heavy lime ores or with concentrate), add to the hot undiluted and unfiltered solution an excess (about 10 c.c.) of a 10% potassium chromate solution. Under these conditions the bulk of the content of the flask will not exceed 50 c.c., and after shaking and letting the precipitated lead chromate settle for about five minutes the content is filtered through an 11-cm. filter of any fairly rapid and close paper. If these directions are carried out the lead chromate will be quite granular, and will show no tendency to run through. The precipitate in the flask and on the filter is washed several times with hot water containing about 0.5% of acetic acid until free from soluble chromates. The funnel with the filter is then set over the original flask and hot dilute hydrochloric acid (1 to 1) is poured through the filter, dissolving the lead chromate. Further additions of hydrochloric acid are

**Jour. Ind. & Eng. Chem.*, Vol. 3, No. 9.

made if necessary and all lead chromate is dissolved from the filter; it is then washed with warm water until free from chromate. The original flask now contains nothing but the hydrochloric-acid solution of the lead chromate and the washings which, after adding a small crystal of potassium iodide, from 0.5 to 2 gm. in weight, is titrated direct with standard 'hypo' solution the value of which is known in terms of lead, the most suitable strength being that in which 1 c.c. is equal to 5 mg. of lead. In this operation, by using only a small quantity of potassium iodide, and having the solution fairly strong with hydrochloric acid (about 50 c.c. of hydrochloric acid, 1 to 1, in a total of 200 c.c. of solution) and somewhat warm, any tendency of the lead to form yellow scales of lead iodide, and thus obscure the end-reaction with starch, is completely checked and the end reaction is sharp."

The sharpness of the end-point with starch, as opposed to the indistinctness of the end-point in the molybdate method, is given as one of the special features. Students working in my laboratory, and chemists in other places, have found difficulties with this method. Sometimes the blue color of the starch disappeared on the addition of thiosulphate, only to come back in a minute or two; in other cases the precipitate of lead chromate seemed not to be washed free from the soluble chromate in the course of an hour or more; sometimes even when no error was visible the results were not concordant. Since the method is exceedingly interesting, I investigated the points of difficulty. I found that treatment of the ore with hydrochloric acid before the addition of nitric acid is to be recommended, since it lessens the tendency to form a globule of sulphur which may enclose some lead. The effect of varying the strength of the acid used in the titration was first tried. To about 10 c.c. of a solution of chromate (9.5 gm. per litre) 200 c.c. of a mixture of strong hydrochloric acid and water, in which the acid varied between 5 c.c. and 100 c.c., was added, and after the addition of potassium iodide the iodine was titrated with thiosulphate. With small quantities of acid the blue color of the starch, after being first discharged, came back after a minute or two. With 5 c.c. of acid the color was discharged and reproduced several times. It seems that there should be at least 25 c.c. of acid present. Titrations in which the chromate had been heated with acid for varying lengths of time between 60° and 80° C. showed in general partial decomposition, though the variations were not always of the order that might be expected. As there is evidently a time-reaction between the chromate, hydrochloric acid, and potassium iodide, the effect of varying amounts of iodide, up to 1 gm., was tested. The most concordant results were obtained by using one gramme of iodide, and by running in the thiosulphate drop by drop, about three drops per second, 1 c.c. of chromate in that case being equal to 1.968 c.c. and 1.976 c.c. of thiosulphate in duplicates. In this set of experiments 25 c.c. of acid, and 175 c.c. of water, were added to 15 c.c. of a chromate-solution measured by a pipette.

One source of error in the method was found to be the solubility of lead chromate in the 0.5% acetic acid used for washing. The addition to 50 c.c. of this acid of 2 or 3 drops of a solution containing less than 1% of chromate rendered its solvent action almost nil, and hence the acid may be used until nearly all the soluble chromate is washed out, but finally pure water is required. In order to avoid possible error from setting chlorine free by the use of half and half hot hydrochloric acid, I dissolved the lead chromate with a cold mixture of 25 c.c. of hydrochloric acid and 75 c.c. of water, washing alternately with this mixture and with cold water. From time to time 5 to 10 c.c. of hot water was used for the more perfect dissolution of the lead chloride.

The precipitate having been dissolved and washed into the flask, as Guess describes, the liquid was made up to about 200 c.c. and 1 gm. of potassium iodide was added, followed immediately, to avoid loss of iodine, by thiosulphate from the burette at the rate of 2 or 3 drops per second. After the brown color had nearly disappeared and had changed to a dark green, starch was added and the thiosulphate run in, a few drops at a time, with vigorous shaking. When the blue color was nearly discharged 10 c.c. of strong hydrochloric acid is added and the flask heated to 40° C., after which 2 or 3 drops of thiosulphate were sufficient to bring the clear green color of the chromic salt, which constitutes the end-point. On four determinations, taking 0.5 gm. of ore there was required 28.30, 28.40, 28.28, and 28.30 c.c. of thiosulphate. The lowest and highest figures give respectively 27.76 and 27.88% lead. The difference between the Guess method of solution of lead chromate and the one here adopted was tested by sprinkling basic lead chromate upon two filters and dissolving one quantity with nearly boiling 1 to 1 acid and the other in the manner described. In the first case 1 c.c. thiosulphate = 0.01516 gm. chromate; in the second 1 c.c. thiosulphate = 0.01446 gm. chromate. Assuming that the second determination was correct, the 0.4336 gm. of chromate used in the first case should have required 29.99 c.c. of thiosulphate instead of 28.60 c.c., which was actually used. With starch iodide paper, chlorine can be readily detected when hot 1 to 1 hydrochloric acid is put upon lead chromate.

In the presence of large quantities of iron, as for example 20%, the tendency to form basic acetate gives difficulty in dissolving the lead. Of course, any ferric acetate precipitated along with lead chromate is fatal. Guess points out that the presence of antimony, bismuth, silver, or gelatinous silica, interferes with the process, but says that if the lead is first changed to sulphate and, after separation from the soluble sulphates, dissolved in ammonium acetate, as for the molybdate determination, the rest of the process may be carried out as before. In this case the sole advantage in the chromate method is its delicacy; it takes a longer time, but duplicate determinations should check within a tenth of one per cent, and often do check within two or three-hundredths.

American Smelting & Refining Company's Tests With Sulphur and Sulphuric Acid on Soils

By P. J. O'GARA

In agriculture it has long been recognized that the essential elements of plant-food are nitrogen, potassium, phosphorus, calcium, magnesium, carbon, hydrogen, oxygen, iron, and sulphur. It is also recognized that other elements, while not essential, are more or less beneficial. It is well understood, of course, that plants cannot use the elements as such, but make use of them in the form of water-soluble compounds; for instance, sulphur cannot be used by the plant as sulphur, but as a sulphate; nitrogen cannot be used as nitrogen but as a nitrate, and so on. Until recent years, although sulphur has been considered one of the essential plant-food constituents, it has been given a relatively secondary place. The earlier analyses of plants showed that sulphur was not found in them in amount equal to some other elements, the element phosphorus being one in point. However, it has been found that the method of analysis for sulphur was faulty and that the more recent method, now in common use in agricultural laboratories, shows a much greater quantity of sulphur present in plants than was heretofore supposed to exist. In fact, the error in the old method of analysis was such that on an average not more than 10% of the sulphur in the plant was recovered, 90% being lost by volatilization. Greater errors than this have been checked against the old method. It is found by comparing the two methods of analysis that plants or portions of plants may show 200 times as much sulphur with the new method as compared with the old. Therefore, the new method of analysis has brought sulphur into prominence as an element of plant-food, indicating that it actually exists in plants in amounts greater, even, than phosphorus. Instead of being an element of minor importance it is now looked upon as an element of the greatest importance.

Experiments to determine the value of sulphur as a plant-food when added to the soil, either as elemental sulphur or in the form of a compound, have been carried out to a considerable extent within very recent years. A number of U. S. Experiment Stations, such as those of Wisconsin, New Jersey, Ohio, Kentucky, Iowa, Oregon, and California, have, within the past few years, made some remarkable discoveries as to the beneficial effects of sulphur when added to the soil as elemental sulphur or as sulphuric acid. Certain European experiment stations have also added to the knowledge of the value of sulphur as a plant-food. Probably the most important work so far done on soils that are somewhat similar to the Utah soils, has been reported by the Californian and Oregon experiment stations. Very recently, and

practically coincident with the work done by the American Smelting & Refining Co. was the work done by Dr. C. B. Lipman of the University of California. His preliminary experiments, although of a more limited character than those carried out by the American Smelting & Refining Co., at its Salt Lake experiment station, gave the first valuable hint as to the beneficial effects of sulphur and sulphuric acid on alkaline soils. His more extensive field experiments have not as yet been reported, but information received from Dr. Lipman shows that the results secured under field-conditions are even more striking than the preliminary pot experiments. Quoting from an important bulletin of the Iowa Agricultural Experiment Station entitled 'Sulphofication in Soils,' by P. E. Brown and E. H. Kellogg: "It is known that sulphur occurs in soils mainly in complex organic compounds, only small amounts of sulphites, sulphates, and sulphides and other mineral sulphur compounds being present. It is likewise known that plants require sulphur in the form of sulphates, and hence it is evident that the process of the transformation of organic sulphur compounds into sulphates is of great importance from the standpoint of the feeding of crops. This transformation or oxidation has been termed sulphofication by Lipman in his admirable scheme of nomenclature for bacteriological processes in the soil, and it will be employed in this work as a general term to include the oxidation of organic sulphur compounds, sulphides, and free sulphur with the production of sulphates." Without going into detail, it may be stated that there are two large groups of organisms which have been described as the red or purple bacteria (*Rhodobacteriaceae*) and the sulphur bacteria or colorless group (*Thiobacteriaceae*). It is these organisms that bring about the oxidation of sulphur to sulphates, in which form the sulphur is available to plants. That these bacteria are of importance has been shown by the lack of sulphofication of sulphur in soils that have been sterilized by heating, this heating process having caused the death of the organisms. A certain amount of oxidation may take place without the aid of soil-bacteria, but this is of very little importance in the economy of plant life in its relation to the soils. The presence of organic matter in the soil is of importance in determining the bacterial flora. Soils with low organic-matter content are found to have relatively few bacteria, therefore such soils would not be greatly benefited by treatment with elemental sulphur as compared with sulphuric acid.

During 1914 and 1915 the American Smelting & Re-

fining Co., on its Utah experimental farm, made a long series of experiments on the effects of sulphur dioxide on soils and on plant-growth. It was shown, for instance: (1) that the water-solubility of the alkali was lowered; (2) that there was a reduction in carbonate; (3) that there was an increase in sulphate; (4) that there was an increase in available potash; (5) that crops fumigated daily throughout their period of growth with sulphur dioxide in concentrations just below the toxic limit, that is, without visible injury to the foliage, showed either a slight gain, or at least no loss in total vegetal matter produced, as compared with check-plots grown under identical conditions but not treated with sulphur dioxide; (6) that the sulphur content of the plants was increased when treated with SO_2 ; (7) that in general the sulphur content of plants is an index of the protein content, that is, high sulphur indicates high protein; low sulphur indicates low protein.

These experiments were carried out with plants grown under normal field conditions of cultivation and irrigation. In general, they were treated just as the regular farm crops on the farm were treated. Therefore, the experiment was in no wise of the laboratory type. As pointed out, the sulphur dioxide, under the conditions of application, did not reduce the yield but rather increased it. Upon analysis of the various plants it was shown that there was an increase in the protein content of the fumigated crops as compared with the untreated check-plots. These important findings were accounted for first, by virtue of the direct effect of the sulphur dioxide on the soil; and second, because of the stimulating effect of the sulphur dioxide on the plants; since it was found that both the soil and the plants readily absorbed sulphur dioxide. These experiments were continued during the year 1916, and the results fully corroborated the work done in 1914 and 1915.

In addition to the experiments with sulphur dioxide gas, field experiments of a somewhat pretentious nature were carried out with elemental sulphur and sulphuric acid during 1916. Summarizing these experiments with sulphur and sulphuric acid it may be said that a very uniform tract of land was selected for the experiments and was divided into three equal parts. The chemical and physical characteristics of the entire tract were extensively uniform. One-third of the tract was treated with elemental sulphur which was carefully spread over the surface at the rate of 400 lb. per acre, and was then harrowed into the soil. Another third was treated with sulphuric acid, 46° Baumé, at the rate of 2172 lb. per acre, this acid having a sulphur equivalent of 400 lb. of elemental sulphur per acre. The other third was allowed to remain untreated as a check. The three tracts were plowed, and the sulphur and sulphuric acid added to the respective tracts on April 18, 1916. All subsequent irrigations and cultivations for all three plots, considering the various crops, were identical, both as to time of application, and amount of water, and the time of cultivation, the purpose being to check out every other factor that might enter into the development of the crops. The

accompanying tabulation indicates the number of crops utilized in the experiment and the results that were obtained.

INCREASE IN CROP YIELDS FROM TREATMENT WITH SULPHUR AND SULPHURIC ACID COMPARED WITH UNTREATED SOILS

Crop	Planted	Harvested	Per cent gain

The accompanying photographs reveal in a most striking manner the results accomplished by treating soils with sulphur and with sulphuric acid. The general superiority of sulphur as a fertilizer stands out prominently. Cut No. 1 shows the effect of a plot treated with 400 lb. of elemental sulphur per acre. The luxuriance of the growth as compared with that shown in No. 2 and No. 3 is most convincing. No. 1 is a similar crop of squash grown on soil treated with sulphuric acid, 46° Baumé, at the rate of 2172 lb. per acre, this being the equivalent in sulphur-content of 400 lb. per acre. No. 3 shows a parallel plot which has received no special treatment. Cut No. 4 reveals the effect of treating the soil with sulphur at the rate of 400 lb. per acre, showing, from left to right, corn, sorghum, millet, Sudan grass, oats, alfalfa, and squash. The corn is over 6 ft. high, the sorghum not yet headed, the millet 3½ ft. high, and the Sudan grass between 5 and 6 ft. high. Cut No. 5 shows similar growths in the same order, grown on soil treated with 46° Baumé sulphuric acid at the rate of 2172 lb. per acre. Cut No. 6 is a check-plot showing similar crops grown on untreated soil. The corresponding yields are given in the foregoing table.

It will be noted that in general the plots treated with sulphur showed a greater gain in total vegetal matter produced than those treated with sulphuric acid. There are, of course, some exceptions, but in general the elemental sulphur produced the best results in the majority of crops. As indicated above, sulphur was applied to the soil at the rate of 400 lb. per acre and the sulphuric acid was applied at a rate sufficient to give the same sulphur equivalent. This is at the rate of about 45 grammes per square metre and indicates, in comparison with several experiments that have been made elsewhere, a maximum application in some instances and a minimum application in others. It may be stated that

our experiments, although carried out under field conditions, were in the nature of preliminary tests. We did not attempt to determine the lower or upper limits of sulphur which would produce maximum results in crop yields. This has been left for further experiments on various soil-types containing varying percentages of alkali and soil-moisture. These experiments are now under way and will be completed during the year 1917, when it is hoped that more definite statements may be made as to the proper amount of sulphuric acid or sulphur to be used in producing maximum results on Utah soils.

In conclusion it may be stated that analyses of the soil of the three divisions into which the field was separated showed: (1) that the water-solubility of the alkali was reduced about 20% in soils treated with sulphur and sulphuric acid as compared with the untreated soils in check-plots; (2) that the availability of potash in the sulphur and sulphuric acid-treated soils was increased approximately 20% as compared with the untreated check-plots; (3) that sulphur and sulphuric acid-treated soils showed an increase of sulphate; (4) that sulphur and sulphuric acid-treated soils showed a decrease in carbonate; (5) that sulphur and sulphuric acid-treated soils increased the yields of all crops with which experiments were made; (6) that sulphur and sulphuric acid-treated soils produced crops with a higher protein-content.

A large number of soil-samples were taken from all three divisions so as to reduce the possible error, and it was found that there was no determinable difference between the effects on the soils treated with sulphur and those treated with sulphuric acid. Aside from the important matter of rendering available more of the potash, the lowering of the water-solubility of the alkali is of importance. The fact that soils having a water-soluble alkali-content somewhat above the limit for general agricultural purposes may be brought under cultivation by treatment with sulphur or sulphuric acid, means that vast areas of now useless lands may be profitably farmed, and that an outlet will be found for the excess sulphur thrown out by smelters as a useless by-prod-

uct because there has been no sufficient market for it.

The important point which all of the above experiments emphasize, is that sulphur, whether it be in the elemental form, in the form of a gas such as sulphur di-oxide, or in the form of a liquid as sulphuric acid, if applied, even in considerable amounts, to alkaline soils not only does not injure the soils but acts in a very bene-

4 Treated with Elemental Sulphur

5 Treated with Sulphuric Acid

6 Check-plot Untreated

ficial way. By inspecting the table given above it will be noted that the increase in the yield in certain crops has been enormous where soils were treated with sulphuric acid and sulphur as compared with the untreated check-plots. While the figures as presented seem almost unbelievable, results secured by other experimenters have been even better. Work done in Oregon by the Southern Oregon substation of the Oregon Agricultural Experiment Station has indicated that yields of alfalfa may be increased up to 500% by the use of sulphur compounds. Many other experimenters have produced greatly increased yields in various farm crops through the use of sulphur and sulphur compounds, so that the value of sulphur as a most important fertilizer is no longer doubted. It is known that large quantities of sulphur are taken from the soil each year by crops, and also that a considerable amount is lost through drainage. It is, therefore, evident that in time the soils become deficient in sulphur. We know that analyses of precipitation taken throughout the various parts of the United States, far removed from the vicinity of smelters, indicate that certain amounts of sulphur are carried down into the soil from the air. However, this amount is small in proportion to the amount used by the plants and that which would be lost through drainage. Hence the necessity of making up the deficiency by the application of fertilizer containing sulphur compounds, or by the direct addition of sulphur or sulphuric acid.

COPPER SULPHATE, obtainable as a smelter waste, has been shown by C. B. Lipman, of the California Agricultural Experiment Station, to possess a remarkably advantageous effect in promoting the nitrification of soils, and the consequent stimulation of plant growth. The nitrification increases from 33 to 100% above that in un-treated soils. Copper produces no toxic effect when present in amounts not exceeding 0.1%, and for many plants much larger quantities may be used. Zinc sulphate is also stimulating, but is more likely to exert a toxic influence.

Finding Logarithms

Have you ever been out in the woods away from a table of logarithms and 'up against it' simply because you didn't have any logarithms to work with? If so, this rough method from *Coal Age* for finding approximate logarithms will doubtless be of interest. It is simple and easily remembered.

Lay off axes *AC* and *BC* at right angles to each other. From the intersection lay off 9 equal spaces to the left, as shown, and mark them 1, 2, 3, 10, from left to right. Then lay off 10 equal spaces upward from the

DIAGRAM FOR FINDING LOGARITHMS

intersection, as shown, and mark them 0.1, 0.2, 0.3, etc. Then, with the extremes *A* and *B* as centres, and the distance *AB* as a radius, find the centre *D*. From that centre describe the arc *AB*. We are now ready to read off the approximate logarithms. For example, what is the logarithm of 4? The dotted line shows how it is found. It is just a hair more than 0.6. Anyone familiar with logarithms will now understand the rest. It is more convenient, of course, to make the drawing on co-ordinate paper, but if this is not handy one can easily do without it and employ plain paper. This method is not claimed to be better than a logarithm table, nor as good, but as a means for obtaining approximate results it will be found to be very close to those tabulated. Best of all is its simplicity and the ease with which it can be remembered. After doing it once it will never be forgotten.

MICHIGAN COPPER AND SILVER IN 1916. The production of copper in Michigan in 1916, reported by the U. S. Geological Survey, was 273,692,525 lb., valued at \$67,328,361, and that of silver was 716,640 oz., valued at \$471,549. This is an increase of \$21,078,251, or 45% over the value of the output in 1915. The average price received for copper for 1916 was 24.6c. per lb., com-

pared with 17.5c. in 1915. The average price of silver for 1916 was 65.8c. per oz. and for 1915 it was 50.7c. The average value per ton of ore treated was \$5.34, compared with \$3.76 in 1915. The smelter production, or the output of refined copper, in 1916 was 269,794,531 lb., which represents an increase of 30,838,121 lb. over the smelter production for 1915. In 1916 the amount of ore milled was 12,364,114 short tons which yielded 420,551,291 lb. of 'mineral' and 268,279,876 lb. copper. In 1915 the amount milled was 12,334,700 short tons, which yielded 400,178,132 lb. of 'mineral' and 265,283,378 lb. of copper. The average recovery of refined copper per ton of ore milled in 1916 was 21.7 lb., compared with 21.5 lb. in 1915.

Production of Rare Metals in Japan

The following figures give the output of rare metal ores in Japan as officially estimated for 1916, and the estimated exports:

Ores	1916	
Output:	Pounds	Value
Antimony	27,333,333	\$7,726,750
Molybdenum	74,167	29,910
Tin	562,666	226,818
Tungsten	1,358,333	747,750
Exports:		
Antimony	19,978,643	4,724,049
Tungsten	1,194,933	417,132

Percentages of metal in the ores are: molybdenum, average 40% (superior 60%); tin, average 40% (superior 78%); antimony, average 60% (superior 71%); tungsten, average 60 to 65% (superior 78%).

THE ELECTROLYTIC ZINC Co. of Australia, Ltd., has begun the erection of a zinc plant at Risdon near Hobart, Australia. It will have a daily capacity of 10 tons of zinc, the works being designed with a view to an increase to a daily output of 100 tons. The plant was erected at Risdon owing to the availability of cheap electric power. The company has a contract with the State hydro-electric department for 4000 hp. per annum, effective January 1, 1918, by which time it is hoped that the works can be started. Arrangements for 46,000 electric horse-power have been made by the company. This electrolytic reduction plant is being built in accordance with the plans used by the Anaconda Copper Mining Co. at its Great Falls zinc works. Construction is in charge of American engineers formerly in the employ of that company, and contracts for machinery and supplies were placed in the United States with the exception of the electric equipment which is being built in England on license from the British government, and will be delivered sooner than would have been possible if contracted with American firms. The cost of the 10-ton plant will be about \$500,000, since the company, in addition to the reduction-plant, is building a private jetty and a tramway for the transport of concentrate from the Broken Hill mines of New South Wales.

The Miami Appeal

Majority Opinion of the U. S. Circuit Court of Appeals, Philadelphia

WOOLLEY, Circuit Judge:

These are appeals from a decree of the District Court in an action brought by Minerals Separation, Limited, a corporation of Great Britain, against the Miami Copper Company, a corporation of Delaware, charging infringement of United States Letters Patent No. 835,120, issued to Sulman, Picard and Ballot, November 6, 1906; No. 962,678, issued to Sulman, Greenway and Higgins, June 28, 1910, and No. 1,099,699, issued to H. Greenway, June 9, 1914, and owned by the plaintiff.

Of the claims in suit the Court found Claims 1 and 12 of the first patent valid and infringed, and Claim 9 invalid; Claims 1, 2, 5 and 6 of the second patent valid and infringed; and Claims 1 to 12 of the third patent invalid. The decree being in parts adverse to both parties, both appealed, presenting for review the same claims, excepting Claim 9 of Patent No. 835,120, with respect to which the appeal is abandoned.

As both parties are appellants, we shall speak of them as they stood in the Court below.

The three patents in suit, to which we shall refer in the order of their issue as first, second and third, are for processes relating to water concentration of ores. They have for their object, stated generally, the separation of metalliferous matter from gangue or barren matter in ore pulp, by means of oils, fatty acids or other substances which have a preferential affinity for metal over gangue. The first patent, while employing the known selective affinity of oil for metal, is based upon a discovery that that affinity is greatest and metal recovery highest when the proportion of oil to ore is relatively least, and upon the disclosure that that property or characteristic may be brought into action and commercially utilized by agitating the ore-bearing pulp until a foam or froth arises to the surface, carrying with it and holding for recovery the extracted metal.

The process of the second patent is distinguished from the process of the first in that the frothing agent is soluble and develops in solution (when agitated to a froth) a selective affinity for metal similar to that of oil, the insoluble frothing agent of the first agent.

The characteristic of the process of the third patent is that concentration may be effected in the cold and without the aid of acid by the admixture of an aromatic hydroxy compound such as phenol or cresol in the place of the insoluble and soluble frothing agents of the other patents and by agitation of the pulp to a froth.

We are aware that this very brief statement of the distinguishing features of the three patents is technically inadequate and will be understood only by those familiar with the history and development of the art of

ore concentration. As that art has been extensively considered and elaborately discussed by scientists and courts both in this country and abroad, in cases in which the invention in suit was involved,* we shall not make even a summary of the art or rehearse the history of this litigation as it has progressed in widely separated parts of the world, but shall rather adopt the whole litigious literature of the invention as matter preliminary to the consideration of the particular issues in this case, repeating only so much as may be necessary to throw light on this new chapter.

FIRST PATENT

The invention of the first patent in suit is based upon a discovery of a wholly unexplained phenomenon arising from the agitation of ore pulp containing oil and air in certain proportions. This was a discovery in an art in which it was well known that the elements of oil, air and agitation possessed certain characteristics and produced certain results.

Haynes, in British Patent No. 488 of 1860, first suggested the use of oil in water concentration of ores by pointing out the affinity which oils have for metallic substances in preference to gangue. Carrie J. Everson showed by Letters Patent No. 348,157, that a small quantity of acid in the pulp aids oil in distinguishing between metal and barren material with which it comes in contact. Elmore (Letters Patent No. 676,679), Kirby (Letters Patent No. 809,959), Froment (British Patent No. 12,778 of 1902), Cattermole (Letters Patent No. 763,260), Sulman and Picard (Letters Patent No. 793,808), and others, employed the known affinity of oil for metal in ore concentration processes by using oil in proportions varying from 2% to 300% on the ore and recovering the oil-coated metal particles by causing them to rise to the top or sink to the bottom of the pulp.

*British Ore Concentration Syndicate, Ltd., v. Minerals Separation, Ltd., 25 R. P. C., 741, High Court of Justice, Chancery Division; affirmed after intermediate reversal in the Court of Appeals by the House of Lords in 1909.

Minerals Separation, Ltd., v. British Ore Concentration Syndicate, Ltd., 27 R. P. C., 33.

Ore Concentration Company, Ltd., v. Sulphide Corporation, Ltd., Supreme Court, New South Wales, 31 R. P. C., 216, 217.

Ore Concentration Company, Ltd., v. Sulphide Corporation, Ltd., 31 R. P. C., 206, Privy Council, British Empire.

Minerals Separation, Ltd., v. Hyde, 207 Fed., 956 (D. C. Montana).

Hyde v. Minerals Separation, Ltd., 214 Fed., 100 (C. C. A., 9th Circuit).

Minerals Separation, Ltd., v. Hyde.

Minerals Separation, Ltd., v. Miami Copper Co., 237 Fed., 609 (D. C. Delaware).

Agitation of oil-impregnated pulp was old in the art. It was employed by Haynes, Everson, Cattermole, Froment, and Sulman and Picard. In these processes, agitation was either gentle or thorough, but never great, and while always employed to produce a thorough oiling of the metal, it was used in different degrees for the sole purpose of causing the metal particles to rise or sink.

Air and other gases were also known and were developed in the form of bubbles to supplement the natural buoyancy of oil and to assist the oil-coated particles to the surface. This use of air was disclosed by Froment in 1902 and again by students of the University of California, in the California Journal of Technology, in 1903, and by Sulman and Picard in the patent referred to (No. 793,808), commonly called the Bubbles Patent.

Thus it may be stated generally that in the prior art, oil was used for its known selective affinity for metal, agitation to mix the oil with the metal, and air to supplement the buoyancy of the oil in raising oil-coated metal particles to the surface. To this extent had the art of oil flotation advanced when the patentees entered it, having reached the commercial stage in only two processes, Elmore and Cattermole, representing respectively metal-flotation and metal-sinking processes, and having reached the stage of success in none.

The Elmore process was known as the bulk-oil or oil-buoyancy process. It required from 100% to 300% of oil on the ore, that is, from 2000 to 6000 pounds of oil to 2000 pounds of ore, and called for a gentle movement or agitation of pulp in a way that would bring the oil and metal in contact without breaking the oil bulk, and relied for metal recoveries on the buoyancy of the oil (due to the lesser specific gravity of the large volume) to raise and hold on the surface the metal which by affinity it had extracted from the ore. This was an oil-flotation process. It was not successful because the cost of the considerable quantity of oil used and not recovered made its practice commercially prohibitive.

The Cattermole process was just the reverse of Elmore. While this process depended upon the utilization of the same selective affinity of oil for metal, the quantity of oil was relatively small, being from 3 to 6% on the ore; but the agitation was considerable, having for its object not the retention of the oil in bulk as in Elmore, but its separation and thorough distribution through the pulp, with the object and result of causing the metal particles to be brought together and agglutinated with the metal slimes, forming granules of a size and specific gravity sufficient to cause them to sink, where they were recovered while the gangue was carried off the surface by an up-flow. This was the metal-sinking process. It had a doubtful success in the concentration of copper and zinc ores of high metal content, but like the Elmore process it was impracticable because unprofitable for the concentration of ores of medium and low grades.

It was while the patentees were engaged in developing this process with a mechanical appliance known as a Gabbett Mixer, by which the pulp was agitated, that the

discovery of the first patent was made. It was found that when the proportion of oil was reduced below 2% the agglutination of Cattermole ceased, and metal recoveries ceased also. This so disturbed the theory upon which the patentees were working that they at once embarked on a series of experiments, in which the quantity of oil was progressively reduced from the Cattermole proportion and the agitation varied in intensity and duration. In experiments with oil in proportions just under the Cattermole proportion nothing resulted. The Cattermole concentration was lost and no other concentration was obtained. When in the line of experiments the proportion of oil to ore was reduced to 1.5%, a "float" appeared. At 1.04% "still more float" appeared. At 0.32% the "float vastly increased." At 0.1% the float again "vastly increased." It thus developed that in using oil at 0.1% or even at 0.05% on the ore, and after violently agitating the pulp from two and one-half to ten minutes, there arose to the surface when the pulp was brought to rest a thick froth or foam of oil-coated air bubbles carrying oil-coated metal particles to the extent of about 90% of the metal content, the form being sufficiently stable to permit removal and metal recoveries.

This was an entirely new result based upon a phenomenon then unknown and still unexplained. It constituted discovery. It was a discovery that promised what has since been accomplished—a change in the art of oil flotation from laboratory experiments and mill failures to commercial success. Its great value, especially in zinc and copper ore concentration, met with world-wide recognition. The art immediately adopted it and paid tribute to it, either by yielding to the patents covering it or by challenging them in litigation commensurate in scope and importance with the field of the discovery itself. The grounds upon which the validity of the patents was attacked were, first, that the phenomenon was already known, and second, that the patentees disclosed no novel means for reducing it to practical use. With the decision of the Supreme Court sustaining the validity of the patent, the two grounds of attack disappeared, leaving open, however, the question whether the discoverers have wholly covered their discovery by a patent, and if not, then how far have they appropriated it to their exclusive use, within the principle that in its naked sense a discovery is not patentable and can be embraced in and controlled by a patent only when and to the extent that its principle is developed into invention by the disclosure of a medium or means which brings it into practical use. *Morton v. New York Eye Infirmary*, 5 Blatchf., 115.

The particular medium by which and through which the discoverers brought into practical action and put to practical use the principle of their discovery, is a process disclosed in their patent. The process described by the claims in suit, including the elements we have numbered and the distinguishing features we have italicized, is as follows:

"1. The herein-described process of concentrating

ores which consists (1) in mixing the powdered ore with water, (2) adding a small proportion of an oil liquid having a preferential affinity for metalliferous matter (amounting to a fraction of one per cent on the ore), (3) *agitating* the mixture *until* the oil-coated mineral matter *forms* into a froth, and (4) separating the froth from the remainder by flotation.

"12. The process of concentrating powdered ore which consists in separating the minerals from gangue (1) by coating the minerals with oil in water containing a fraction of one per cent of oil on the ore, (2) *agitating* the mixture *to cause* the oil-coated mineral *to form* a froth, and (3) separating the froth from the remainder of the mixture."

The claims disclose the process. The specification, as usual, throws light upon the process by distinguishing it from the prior art, describing its operation and result, and referring to illustrations of its practice in two apparatus, in one of which agitation and consequent aeration and fomentation are accomplished by mechanical means.

The validity of this patent and of its equivalent abroad has been widely attacked and ultimately sustained. As our task is to interpret the scope of the United States patent, we shall concern ourselves only with the decisions of the courts of this country.

The first suit on the patent was brought in the District Court of the United States for the District of Montana (*Minerals Separation, Ltd. v. Hyde*, 207 Fed., 956). The validity of the patent was attacked on the ground of anticipation by the prior art, but the Court held the patent valid and found invention in the novel and useful combination of oil, air and agitation (*Minerals Separation, Ltd., v. Hyde*, 207 Fed., 956, 961).

The United States Circuit Court of Appeals for the Ninth Circuit, reversing on appeal the decree of the District Court, found the patent invalid, on the ground that its only novelty lay in the reduced quantity of oil, that this was an improvement only in degree and therefore did not involve invention (*Hyde v. Minerals Separation, Ltd.*, 214 U. S., 100).

The case was then removed by certiorari to the Supreme Court of the United States, and while there awaiting hearing, the action at bar was instituted in the District Court of the United States for the District of Delaware (*Minerals Separation, Ltd., v. Miami Copper Co.*, 237 Fed., 609).

In this case the District Court held the patent valid and infringed, finding (in opposition to the Circuit Court of Appeals for the Ninth Circuit) patentable invention in the use of oil in the minute proportion of the patent.

Shortly thereafter the Supreme Court heard argument and entered a decree in *Minerals Separation, Ltd., v. Hyde* by which it reversed the decree of the Circuit Court of Appeals for the Ninth Circuit and held the patent valid, finding invention, as we read the opinion, in the co-action of the critical proportion of oil and air effected by "an agitation greater than and different from

that which had been resorted to before," resulting in a froth concentrate of economical value.

Following the decree of the Supreme Court in *Minerals Separation, Ltd., v. Hyde*, this case was argued before us. The decree of the Supreme Court, with its accompanying opinion in the Hyde case, materially changed the aspect of this case on appeal by contracting, and in a sense expanding, the issues as tried by the District Court. It disposed of the issue of validity, which had been vigorously contested in the Court below. But in disposing of that issue upon grounds different from those upon which the District Court based a like judgment, the question of infringement was acutely enlarged. Upon the finding by the District Court that patentable invention resides in the critical proportion of oil, the admitted use of oil in that proportion by the defendant was manifestly controlling in its finding of infringement, although the defense extended to the whole of the defendant's practices. But under the finding by the Supreme Court in the Hyde case that invention resides not alone in the critical proportion of oil but also in air and agitation, we are called upon to construe the patent in the light of that finding and determine whether the defendant's practices of aeration and agitation in connection with its admitted use of the critical proportion of oil, are within or beyond the scope of the patent.

It is to be noted and kept in mind that the Supreme Court did not construe the patent or determine its scope, for it had no occasion to do so. In the case before it, infringement was so clear that it had to be found if the patent was valid. The validity of the patent, therefore, was the only seriously controverted issue before the Supreme Court.

In deciding the issue of validity, the Supreme Court disposed of the prior art as anticipations by reviewing by general classification its processes together with the process of the patent, and in so doing used expressions which the parties have severally employed in support of and in opposition to their respective contentions. The plaintiff maintains that the language of the Supreme Court supports its broad contention, that "Whenever the modifying agent of the patent (oil) is used, a person infringes who gets air into the pulp in any fashion and agitates the mixture by any means to a sufficient extent to cause the mineral particles to attach themselves to air bubbles and to rise therewith above the top of the mixture in a collection of bubbles and metal particles, to wit, froth." The defendant maintains that the agitation in which the Supreme Court found invention, is agitation produced by mechanical means, and that anyone, who, though using the modifying agent of the patent in the critical proportion, introduces air into the pulp otherwise than by beating it in, and who agitates the pulp to a metal-bearing froth by any means other than mechanical, or who otherwise obtains the result without any agitation whatever, is beyond the scope of the patent and escapes infringement.

Considered in the light of what the Supreme Court said and what it did not say, it is clear that the positions

of both parties are extreme. The contention of the plaintiff at least omits the very definite limitation of the patent to the results obtained by the use of oil within the described proportions, and also the equally definite disclosure of an agitation in violence and duration greater than before employed, while the defendant misinterprets words of description as words of limitation.

The Supreme Court said that:

"The process of the patent in suit, as described and practiced, consists in the use of an amount of oil which is 'critical' and minute as compared with the amount in prior processes * * * and in so impregnating with air the mass of air and water by agitation—'by beating the air into the mass'—as to cause to rise to the surface of the mass, or pulp, a froth particularly coherent and consistent in character * * *."

By this expression the defendant maintains that the Supreme Court did not merely repeat testimony describing and showing how the process was practiced, but used the words as their own, and thereby interpreted the patent and limited its scope to the introduction of air into the pulp "by beating the air" into the pulp by the specific mechanical means illustratively shown by the drawings of the patent. We do not so interpret this expression. In the first place, the patent nowhere uses the words "by beating the air into the mass." Therefore these words as quoted by the Supreme Court were not quoted from the patent, but were taken from the testimony of a witness who used them in describing the process as discovered and developed by the patentees. This being so, we do not think these words, as used by the Supreme Court in describing the process, can be construed as a limitation upon the process.

It further appears that the Supreme Court in distinguishing the process of the patent from processes of other patents relied on as anticipations, found that the lifting force which separates metallic particles of the pulp from other substances resides chiefly "in the buoyancy of the air bubbles introduced into the mixture by an agitation greater than and different from that which had been resorted to before." By this expression the defendant insists that the Court explicitly limited the patent to agitation caused by mechanical means, thereby excluding from its scope such agitation by pneumatic means as was used in part in the defendant's practice. As this expression is susceptible of an entirely different meaning, presently to be considered, we find nothing said by the Supreme Court which indicates that it limited the agitation of the patent to agitation by mechanical means.

The defendant further maintains that the Supreme Court gave to the patent a narrow construction when it used these words:

"While we thus find in favor of the validity of the patent, we cannot agree with the District Court in regarding it valid as to all of the claims in suit. As we have pointed out in this opinion, there were many investigators at work in this field to which the process of the patent in suit relates when the patentees came into

it, and it was while engaged in study of prior kindred processes that their discovery was made. While the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, turned failure into success (*The Barbed Wire Patent*, 143 U. S., 275), yet the investigations preceding were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportion' amounting to a fraction of 1% on the ore. * * *"

We are inclined to the opinion that by this expression the Court intended a limitation only upon that one feature of the patent to which the expression was addressed. The District Court had held valid certain claims in which the proportion of oil was described simply as "a small quantity," and the Supreme Court in reversing that finding and holding those claims invalid, used the quoted words of limitation in confining the patent to the results obtained by the use of oil in the critical proportions of less than 1%.

From this recital of the litigation of the invention of the first patent it appears that in construing the claims of the patent we are greatly aided by the opinion of the Supreme Court in being told with authoritative finality that the process involves invention and in being shown in which of its elements invention resides; but it is equally clear that in determining the breadth and scope of the claims, we are without the aid of any adjudication in which their scope has been decided, or even considered.

The elements of the patent in which invention is found are oil, air, and agitation. These were old in the art, possessing in the process of the patent no new or different function, or had they produced no new or different result, it is clear they would have anticipated the patent and defeated its claim to invention. But a finding by the Supreme Court that the invention was not anticipated by the old uses and results of these elements is, in effect, a finding that these elements as used in the process of the patent perform or develop new uses and functions or produce different results. And such we find to be the fact.

The invention, as we have said, is founded upon a discovery. Its patentability depends upon the medium disclosed in the patent by which the force or principle of the discovery is brought into action. Three new uses of old elements are disclosed in the patent, producing a new result. The first relates to oil.

The affinity of oil for metal was known, and though old, was employed in the invention; but that this affinity in a given condition is greatest when its quantity is relatively least or that the affinity increases with the decrease of oil below a given quantity (less than 1%), is the soul of the discovery and was wholly new. But the discovery did not consist of this alone. The newly discovered phenomenon of the minute quantity of oil is not a chemical phenomenon. Oil in pulp in minute quantity, if inert and left alone, will do nothing and produce

nothing. Something must be done to develop it. The phenomenon not being susceptible of development by chemical change, is developed by physical change of the pulp. As a medium or means of producing that change and creating the condition under which the phenomenon arises, the patentees pointed out—agitation.

The agitation of the patent does several things, old and new. It mixes the oil with the metal of the ore. This is old. Then, by its greater intensity and longer duration, it stirs the pulp into a froth, developing at once its own new use as a frothing means, and still another new function of oil—that of a frothing agent. Both are new.

But froth is made of air as well as oil. Air in bubbles is used for its old function of assisting or escorting metal particles to the surface. But it is also used for the entirely novel purpose of supplying one of the essential elements of froth, froth being the new result intended.

Thus, oil is used for its newly discovered characteristics of greater metal affinity when in minute quantity and for its new function as a frothing agent; air for the new purpose of supplying an element of froth; and agitation for its new purpose of bringing the two together and causing them to co-act and produce the new result of a metal-carrying froth. In other words, in so employing these old elements for new purposes, the new things which the patentees told the art that a radical decrease of oil in conjunction with a radical increase of agitation, develops to its highest potentiality the known affinity of oil for metal, and produces a physical change in the pulp in the form of a froth by which metal recoveries are made possible and commercially profitable. The importance of these disclosures, scientifically and commercially, is manifest.

In approaching a consideration of the scope of the patent, we lay aside those features of the discussion in which the plaintiff demands by broad construction the highest reward for a great contribution to a feeble art, and in which the defendant, contending for a narrow construction, emphasizes the servitude of a great art to a patent monopoly. The rights of an inventor and of an art in an invention are established by law and are not affected by other considerations. Speaking generally, the statutes give an inventor a patent monopoly of his invention to the extent of his patent disclosures, and to that extent the art is servient to his monopoly. Everything touching the invention not disclosed by the patent is free to the art without regard to the value of the inventor's contribution. So the question of law in this case, involving as it does large interests and perhaps far-reaching commercial results, is no different from similar questions constantly appearing in controversies of smaller compass. The question simply is whether certain practices come within the scope of the patent claims. But the question of infringement has grown far beyond the borders of the case and we are really asked both by the plaintiff and defendant to determine the scope of the patent in such terms as will inform the art as well as the

owners of the patent the precise field covered by the patent and the extent of the field left free to the art. Such a decision to be useful must of course be predicated upon facts that make it legally possible, for otherwise we encounter the futility and the mischief of construing a patent in general terms and without reference to the occasion or thing which call for its interpretation. To avoid this error we shall confine ourselves to the precise issues of this case as developed by the evidence, and without regard to other considerations we shall construe the patent with reference to the particular practices which are represented by one party to be within its scope and by the other to be beyond it.

The defendant practiced four processes of ore concentration using in all the fomenting agent of oil in the critical proportion of the patent. Two processes were practiced before suit was instituted, the third during the progress of the trial, and the fourth after the record had been completed and the trial closed. As the infringement found by the decree relates to the processes appearing in the record, only those processes are before us on appeal.

FIRST PROCESS. The defendant company owns and operates a large porphyry copper mine at Miami, Arizona. The ore is low grade and of a kind peculiarly responsive in concentration to the process of the patent.

The defendant employed a metallurgical mining engineer to develop and install in its reduction works an oil-flotation concentration plant. The engineer made repeated visits to the mill of a neighboring copper company, a licensee of the plaintiff, studied the process of the patent there in practice, and reproduced it in the mill of the defendant. This was a small plant, of a capacity of but two tons per hour or forty-eight tons per day, operated during the period from December 1913 to August 5, 1914. It was used evidently more as a testing or experimental plant for another process than being developed for commercial purposes.

This constituted the defendant's first process, and as infringement was not disputed, we affirm without discussion that part of the decree holding infringement by this process.

SECOND PROCESS. On August 7, 1914, two days after the discontinuance of the first process, the defendant started its second process in a plant which it had constructed during the practice of the first. This plant may best be understood by a diagram furnished by the defendant and by its own detailed description of its operation appearing in its brief.

"The material treated in the flotation plant at Miami, is received through the launder or trough A, the same bearing the legend 'Original Pulp Feed.' This material is a freely flowing pulp, and flows into the box or tank B, upon which the following inscription appears, 'Sump from Which Pulp is Pumped.' The oil or other modifying agent is supplied to the pulp through the pipe L, marked 'oil feed.' A centrifugal pump C raises the pulp from the pipe L, marked 'oil feed.' A centrifugal pump C raises the pulp from the sump B, and forces it

upwards through a pipe D, from which the pulp passes into an inlet funnel E. The pulp flows from the funnel E downward through a pipe F and enters the Pachuca tank G through the side thereof, as shown in the drawing. A small air pipe H, extends downwardly from the top of the Pachuca to a point near the bottom thereof, where it delivers an air jet at the point designated I. The small air pipe H is surrounded by a larger pipe J, open at both ends. There is an annular space between the pipes H and J, and the air entering the lower end of the large pipe J, through the pipe H, permeates the pulp contained in the pipe J with small bubbles, which have the effect of forming a mixture of air and pulp of lower specific gravity than the pulp alone. The lightened column of air and pulp in pipe J rises and is projected against a conical deflector K, and then falls into the main body of the Pachuca. The circulatory movement of the pulp in the Pachuca tank has the effect of thoroughly mixing the oil with the pulp. The pulp flows from the top of the Pachuca tank into a box M, whence it is conducted by the launder or trough N to the air cells, marked 1, 2, 3 and 4.

"The air cells 1, 2, 3 and 4 are similar in construction. The bottom of each cell consists of four plies of canvas, beneath which are eight air compartments, separate and distinct from each other, extending in a series from end to end. The canvas bottom of the machine is inclined, thus making the cell deeper at one end than at the other, and it is for the purpose of getting an even distribution of air that the eight compartments are used, it being obvious that if there were a single air compartment most of the air would escape at the shallow end, where the water pressure is least. Air under slight pressure is supplied to the compartments beneath the cells 1, 2, 3, 4 and 5, by means of a blower designated by the letter M upon the drawing. The air is conducted through a pipe marked 'Air Main' from the blower, and branch air pipes, shown most plainly at the right of cell No. 1, conduct the air to the several compartments beneath the cells. The degree of air pressure necessary is quite slight, and, as stated by Mr. Yerxa, it is necessary to use merely enough pressure to overcome the hydrostatic head of the pulp and to force the air through the permeable medium, that is, the canvas bottom.

"The air so pumped beneath the canvas bottoms of the cells 1, 2, 3, 4 and 5, passes upward through the pores of the canvas into the pulp, and the bubbles rise through the pulp in a manner similar to the rising of the bubbles through a glass of carbonated water."

For the purpose of this discussion, the details of the apparatus and of its operation may be simplified by referring to its four essential parts: C, centrifugal pump; E, a break or open space between the pipe of the pump and the Pachuca tank which does not appear on the diagram or in the defendant's account of the operation; G, Pachuca tank and its appliances; and 1, 2, 3, 4 and 5, Callow cells.

Before following the steps or rather the flow of the defendant's process, we should have in mind the theory of

its practice. The defendant maintains that the process of the patent is "an *agitation* froth process," that is, a process by which the desired metal-bearing froth is obtained by agitating pulp containing the critical quantity of the frothing agent (oil) "to cause" the froth to arise or "until" a froth is formed. It says that its process, in contradistinction to the process of the patent, is a "*bubbles* process" (containing the same critical quantity of the same frothing agent), by which air, introduced into the pulp from below, passes through the pulp "without any agitation whatever," and arises to the surface in short-lived evanescent metal-bearing bubbles forming a "*foam*." It maintains that by introducing air into the pulp by sub-aeration it produces a foam or froth otherwise than by agitation, that nowhere in the process is there agitation, or that, at most, there is only such agitation as appears in the prior art.

Agitation "to cause" a froth or agitation "until" a froth is formed, being the disclosed means of the patent to produce the phenomenon of the critical quantity of oil, and aeration without agitation being the defendant's claimed means of causing or obtaining the same phenomenon from the same critical proportion of oil in the form of an evanescent foam, the controversy revolves around the elements of aeration and agitation.

C. *Centrifugal Pump.* The first step in the defendant's process was a centrifugal pump. The defendant claims its one function was that of lifting the pulp (containing oil in the critical proportion of the patent) from one floor of the mill to another, and that in doing so the pulp was neither agitated nor aerated. Opposed to this contention and to the testimony supporting it was testimony that a centrifugal pump drawing air and liquid was the most common type of agitator and aerator of the cyanide art before the Pachuca tank was invented; that in the defendant's apparatus air was drawn with the liquid into the pump in large quantities; and that in revolving at the rate of 850 revolutions per minute the pulp was violently agitated and measurably aerated.

Reconciling the conflicting testimony as best we may, we are forced to the conclusion that the pump revolving at the rate of 14 revolutions per second could not well avoid agitating the liquid it hoisted; that the agitation was violent; that air was drawn in with the liquid and that to an extent the pulp was aerated within sense of the agitation of the patent and also by the very mechanical means or its equivalent to which the defendant insists the patent is limited.

E. *Break in the Circuit.*—At the point E in the pipe between the pump and the Pachuca tank there was a break not appearing in the diagram, permitting the pulp, arising from the pump in its agitated and partially aerated state, to drop for a space through the air into a larger pipe, whence it was carried to the Pachuca tank. While this was not a prominent feature of the defendant's process it was of sufficient consequence for the defendant to use it. It had the effect of producing further agitation of the pulp in its fall and further aeration arising from that agitation. It was known as

splash agitation, its principle appearing in the early attempts to purify water by aeration. We are satisfied that this constituted agitation and aeration by agitation, and again by mechanical means to which it is sought to limit the patent.

G. Pachuca Tank.—The pulp twice agitated and aerated was then carried without stopping into a Pachuca tank. This appliance, briefly described, is a tank 18 feet 6 inches high by 4 feet in diameter. Descending in its centre are two pipes or columns, one within the other, and in operation compressed air is released through the inner one, sending the fluid in an upward current through the outer one until it strikes with force an overhanging cone or umbrella, which causes it to splash and fall back into the tank, to be subjected again and again to the same revolving movement for a period of time measured by minutes.

The Pachuca tank was taken from the cyanide art, where its one function was agitation and aeration, or rather aeration by agitation. Although agitation is denied by the defendant to be a part of its process, it cannot be seriously contended in the face of the testimony and of the demonstration of the action of the Pachuca tank before us, that the force of compressed air to which the pulp in the tank is subjected, does not cause agitation and very violent agitation.

But the defendant contends that the agitation of the patent is limited to agitation occasioned by mechanical means, and as the agitation in the Pachuca tank is caused by pneumatic means, it is beyond the scope of the patent. This contention is based not alone upon the words of the Supreme Court which we have already discussed, but upon the relation of a mechanical device to the discovery of the invention.

It appears that in the experiments in which the discovery was made, the inventors agitated various mixtures by an apparatus known as a Gabbett Mixer, and when they came to reduce their discovery to invention and patent it they illustrated diagrammatically "one form of apparatus suitable for carrying this invention into practice," which included such a mixer. The patentees did not attempt to patent a mechanical means by which their process could be practiced. This is obvious, for the means illustratively shown was a mechanism already patented (No. 444,345, Gabbett Mixer, 1891). Nor did they attempt or intend to limit their patent to any mechanical means. Their patent was for a process. But without regard to their intention, did they in fact so limit it? That depends upon what they disclosed by their patent.

By their disclosures they first told the art that a maximum metal recovery could be had from a minimum oil content. Up to the time of this disclosure that was an unknown phenomenon. But this disclosure alone, interesting as it was, would have been valueless to the art, and would not have entitled the discoverers to a patent, until they told how and by what medium that phenomenon could be brought into practical use. Knowing this, they then told the art by the same disclosures that the

minute quantity of oil, besides possessing an affinity for metal, was a frothing agent, and when used as such a phenomenon appeared in the froth it developed. But patentees did not stop with the disclosure that fomentation is the condition out of which the phenomenon arises, but proceeded by further disclosures to tell the art that the way to produce the desired fomentation is by agitating the pulp containing the frothing agent. But agitation of certain kinds for certain purposes was well known, so they went further and told what was not known, namely, that the agitation requisite to fomentation of the character desired, is agitation "greater than and different from that which had been resorted to before," that is, greater than the more or less brisk or vigorous test-tube agitation of early patents and of the Cattermole process, and different from the revolving gentle agitation of the Elmore bulk-oil process, and that it must be violent in character and extended in duration in order that air (the other element of fomentation) might be brought into the fluid and into co-action with the minute quantity of the frothing agent. They thus disclosed not only agitation, but the kind of agitation as the medium or means by which the principle of their discovery could be reduced to practice. Agitation was thus made the practical element of their patented process, and by their patent disclosures they told the art that agitation was the secret by which the principle of their discovery could be unlocked and used.

If the same principle can be turned to use and the same results obtained without agitation, or by an agitation which is not the equivalent of the agitation of the patent disclosures, we may have another question; but when the critical quantity of oil is used and fomentation is produced by agitation, which in degree of violence and in duration is substantially that of the patent, clearly it is indifferent whether it is attained by mechanical or other means, for the patent deals with agitation as a means of developing the discovery, not with means for developing agitation.

Accepting the teaching of the patent with reference to agitation as a means, the defendant employed it, certainly in three, if not in four, of the steps of its process. In the first and second, agitation was obtained by mechanical means; in the third (the Pachuca tank), by pneumatic means. It is upon this difference in means to produce agitation that the defendant, in part, defends the charge of infringement. But what it sought and what it got by the use of the Pachuca tank was agitation, and that is what the patent told it to get, and we conceive it makes no difference whether it got it by mechanical or pneumatic means. We see no difference between the blow of a paddle and the blow of a blast of air as means to produce agitation. And the defendant itself shows there is no difference between the two in procuring the agitation of the patent, for by agitating the pulp in the Pachuca tank by pneumatic means with an intensity and for a period of time sufficient to aerate the pulp, the defendant got the precise metal-bearing froth of the patent. This was unintentionally and ae-

identally shown on one occasion when the Pachuca tank was cut out of the process and the pulp brought to rest. The characteristic froth of the patent arose at once and formed in a collar two feet thick. In view of the agitation to which the pulp had been subjected, we must assume that it was the result of that agitation.

Thus far the defendant did everything that is disclosed by the process of the patent. It used the critical quantity of oil. This is admitted. It agitated the pulp by one means and another with an intensity and for a time sufficient to change the physical character of the pulp, as intended by the patent, and developed in it the quality of producing an air-bearing froth, which it did when permitted to come to rest. But in the practice of the defendant, agitation was not stopped or even arrested in the Pachuca tank. The pulp was carried in circuit without stopping and without abatement of agitation into Callow cells, carrying with it the air content accumulated by the agitation of the centrifugal pump, the air drop and the Pachuca tank.

1, 2, 3, 4, 5. *Callow cells.*—As a last step, the pulp was conveyed into Callow cells. A Callow cell is a rectangular tank with a sloping bottom made of canvas, through the perforations of which compressed air ascends in myriads of air bubbles through the liquid it contains. By this process, the defendant contends it pursued a practice taken from the prior art and entirely outside the scope of the patent.

In this connection much stress has been placed by the defendant upon the prior art, on the theory that as the Supreme Court found the invention not anticipated, all that the prior art contains is open to it without the hazard of infringement. This position is unobjectionable. It is clear that if the defendant practiced the process of the patent and obtained a different result, or if it practiced a different process and obtained the same result, it did not infringe. To do this it was free to resort to a practice of the prior art or to a practice new to the art. It chose to rely upon a practice of the prior art, which, though producing the same result in metal recoveries as that of the patent, it maintains, differed from it in its steps and means. It was based upon Patent No. 793,808 granted to Sulman and Picard (two of the patentees of the patent in suit), and commonly called the Bubbles patent. This patent, though it never reached the mill, has been extensively discussed by experts and counsel. Air is introduced into the bottom of a tank similar in shape to that of a Callow cell. Near the bottom is a perforated helical worm or tube, through which, while revolving, air is permitted to escape and ascend in bubbles to the surface. As the pulp is modified by oil (not the critical quantity of the patent) the air bubbles and metal particles are coated with oil, whereupon the oil performs its known affinity for metal, and air its known characteristic to ascend and assist the oiled metal to the surface.

While there is a similarity in principle between the mere introduction of air in the Callow cell and in the Bubbles tank, the purpose for which air is injected and

the function which air performs after it is injected are altogether different in the two. Before the pulp is put into the Bubbles tank it is agitated for the purpose of mixing the oil and coating the metal particles, and when that is done it is turned into the Bubbles tank where the air bubbles, liberated through the perforations of the coil, attach themselves to and escort the oil-coated metal particles to the surface, where they are carried off by skim flotation. In the Callow cell of the defendant's process (the claimed equivalent of the Bubbles tank) air was used for another purpose. The pulp, first agitated to the potentiality of the critical quantity of oil and air of the patent, was carried into the Callow cell, and with its elements thus fully developed was subjected to an air blast, which did two things, resulting in a third. First, the air blast further aerated or super-aerated an already fully aerated pulp by driving into it myriads of air bubbles, and second, caused an agitation which while considerable was not violent, resulting in a foam, which persisted so long as air pressure was maintained, and which had a metal-bearing quality and sufficient stability to permit recovery by overflow.

A peculiar feature of this step in the process and upon which the defendant earnestly relies to distinguish it from that of the patent, is, that if the pulp agitation of the Callow cell is arrested by withdrawing the air pressure, the foam immediately subsides and the froth of the patent does not arise as it did when agitation was arrested in the Pachuca tank. This is true. It is equally true that in this fourth step, aeration is direct and is not the result of or caused by agitation. On the contrary, agitation results from aeration, and such agitation, though present in some measure, is not even approximately of the violence and duration of the agitation of the patent. The operation in the Callow cell certainly possesses these distinguishing features from operation of the process where aeration is caused by agitation. Emphasizing this difference in its favor, the defendant pressed further and urged that the operation of the Callow cell was not dependent upon the precedent treatment of pulp in the Pachuca tank, and that the same results could be obtained from the Callow cell without such previous agitation and aeration. This assertion is based upon an experiment made by the defendant in the presence of representatives of the plaintiff when the Pachuca tank was cut out of the system and pulp from the centrifugal pump was shunted directly into the Callow cells, with the result that the Callow cells continued to perform their function of supplying air bubbles, agitating the pulp to a degree and forming an overflowing metal-carrying foam. But the metal carried over was not assayed and we do not know what were the commercial results of the test. We know, however, that this was but an experiment and after the experiment had been concluded, the defendant returned immediately to its practice of using the Pachuca tank. Nor are we informed as to what would happen if the centrifugal pump had also been cut out, because whether in the mill or in the laboratory, so far as we have been

shown, it appears that *before* the Callow cell (or Bubbles tank) is called upon to perform its task, the pulp is always pre-agitated and pre-aerated in some fashion and to some extent. Even in the demonstrations of the Callow cell and the Bubbles tank made before us in court, the defendant's demonstrator caused the pulp to be violently agitated by a *Gabbett mixer*, the illustrated means of the patent, for a period of time measured by a stop-watch before it was turned into the cell and tank.

Notwithstanding the defendant's testimony is silent as to what a Callow cell would do to pulp that had not been previously agitated and aerated, and notwithstanding all Callow cell demonstrations before us were made with pre-agitated and pre-aerated pulp, the case for the defendant was largely argued as though its process consisted solely in passing thoroughly mixed but quiescent pulp directly into Callow cells, where it received its first and final aeration without previous or present agitation, resulting in a metal-bearing foam with characteristics different from those of the froth of the patent. We find nothing in the evidence or in the demonstrations which justifies that argument. If the only agitation to which the pulp was subjected (after such agitation as in the prior art was necessary to mix the oil and ore) was the agitation of the Callow cells, we would not say that that agitation amounted to or was the equivalent of the violent agitation of the patent disclosure and constituted infringement; but in the process we are considering and upon which the decree we are reviewing was based, the Callow cells were not the whole process but were merely the last of four distinct parts of the process, the other three being the process of the patent or its fair equivalent. Having used the process of the patent in the first three steps in developing in the pulp the potentiality of the critical quantity of oil and air and in bringing the pulp to the point where, if permitted, it would produce the result of the patent, we feel that the defendant cannot escape infringement by taking an additional step, even though that step if taken alone avoids the patent.

THIRD PROCESS. The third process of the defendant was developed and put into practice during the trial and constituted one of the defenses to the charge of infringement. There is little difference between it and the second process. It is shown by the accompanying reproduction of a blueprint of the apparatus in which it was practiced.

The plant is shown to comprise two independent sets of flotation cells, one at the right and the other at the left of the drawing. The flotation cells are designated—"4—Roughing Cells" and "2—Cleaner Cells." Adjoining each group of cells is a Pachuca tank. The operation begins upon the 22 concentrating tables, so numbered upon the drawing. The material rejected by these tables is treated by the flotation process. The flow of pulp in the tables through the launders takes place by gravity until the pulp reaches a bucket elevator, which is the substitute for the centrifugal pump in the second process. When the pulp is raised by the elevator to an

upper floor it is divided and flows in equal parts into two Pachuca tanks, thence to the Callow cells, where metal recoveries are obtained by froth overflow.

The value of this process, as a defense, is found in an experiment to which it was subjected. The plant was arranged in two groups of identical members. In the experiment, one group was operated with the Pachuca tank as planned. In the other, the Pachuca tank was cut out and the pulp conveyed directly from the elevator to the cells. The result was no apparent difference in the action of the pulp and little difference in the assays of the metal recoveries, that difference, curiously enough, being in favor of the group in which the Pachuca tank was not used. The evidence of the fact and of the effect of this experiment was not contradicted, except, perhaps, by the defendant itself, by returning at once to its previous practice of using both Pachuca tanks, and in pursuing that practice to a time beyond the trial. This fact places the third process in the position of the second, where we have found that agitation and aeration of the Pachuca tank is the agitation of the patent, and amounts to infringement.

FOURTH PROCESS. The fourth process is not in the record and was not considered by the District Court in reaching the decree now before us on appeal. It was brought to our attention during the argument by counsel, who said that in the process developed by the defendant after the trial, and now practiced, the Pachuca tanks are eliminated, the pulp being delivered directly from the bucket elevators to the Callow cells. While we are loath to omit from our consideration and judgment anything affecting this very important patent and the art to which it relates, we feel, nevertheless, that we cannot consider and adjudge with propriety or authority a process with respect to which the plaintiff has had no opportunity to produce testimony and which was not embraced in the decree we are reviewing.

We find no error in the decree of the District Court holding valid and infringed Claims 1 and 12 of the first patent in suit.

SECOND PATENT

The second patent involved in this suit, No. 962,678,—also for improvements in ore concentration—was applied for on April 30, 1909, was issued on June 28, 1910, to Sulman, Greenway and Higgins, and has not been judicially passed upon except by the Court below. Its particular object is "to separate to certain constituents of an ore such as metallic sulphide from other constituents, such as gangue, when the ore is suspended in a liquid such as water."

It is also an air-froth flotation process but differs from the first patent although both processes may be, and both actually are, employed conjointly. Its essential feature is the use of a mineral-frothing agent in solution, and the method will be best understood by turning to the specification:

"According to this invention the crushed ore is mixed with water containing in solution a small percentage of a

mineral-frothing agent (that is of one or more organic substances which enable metallic sulphide to float under conditions hereinafter specified) and containing also a small percentage of a suitable acid such as sulphuric acid, and the mixture is thoroughly agitated; a gas is liberated in, generated in, or effectively introduced into the mixture and the ore particles come in contact with the gas and the result is that metallic sulphide particles float to the surface in the form of a froth or scum, and can thereafter be separated by any well-known means. Among the organic substances which in solution we have found suitable for use as mineral-frothing agents with certain ores are amyl acetate and other esters; phenol and its homologues; benzoic, valerianic and lactic acids; acetones and other ketones such as camphor. In some cases a mixture of two such mineral-frothing agents gives a better result than a single agent. The above mentioned mineral-frothing agents are all more or less effective in the presence of an acid such as sulphuric acid and are given as types but are not intended to form an exhaustive list of suitable organic substances which may be used in this manner and for these objects. On the other hand, there are many organic compounds which in solution will not effect the result described, such as some sugars, dextrin, saponin, albumen, ox gall, etc., and a simple test is required in the case of varying ores or materials to determine which organic compound is most suitable.

"The following is an example of one method of carrying this invention into effect: Water containing a small percentage of sulphuric acid in solution, say from 0.2% to 0.5%, and containing in solution a small quantity, say 0.1% of one of the foregoing organic substances (say amyl acetate) is, with finely pulverized ore, introduced into an agitating apparatus, in the proportion of say 3 parts by weight of water to 1 part by weight of ore. The agitation is carried out in such a way as thoroughly to disseminate air through the mixture which is thereafter discharged into a spitzkasten. It is found that a coherent froth or scum floats on the surface of the water in the spitzkasten. This froth contains a large proportion of the metallic sulphides but is substantially free from gangue. Any well-known means may be employed for collecting the froth. If desired the tailings can be retreated by the same process with or without the addition of fresh quantities of the organic materials referred to. The action may in some instances be improved by heating the mixture.

* * * * *

"Several agitation vessels are placed in series. These may be conveniently large vats separated by partitions having openings at the bottom so that the liquid may pass from one to another. Each vessel is provided with a rotatable stirrer which is conveniently of the form shown in the drawing. Each stirrer is carried on a spindle rotated at a high speed by any convenient means. Crushed ore or similar finely divided mineral is fed into the first vessel through any convenient ore-feeding device * * *, and water is also fed into the vessel. A small proportion of acid, such as sulphuric acid, may be intro-

duced into the water from the feeding vessel, and a small proportion of one or more other soluble substances which enable metallic sulphides to be floated by air under the conditions hereafter specified, may be introduced from the feeding vessel. The liquid containing ore in suspension is vigorously agitated in the agitation-vessels and escapes at the outlet highly charged with air.

"A settling apparatus consisting of one or more spitzkasten is placed immediately at the outlet from the agitation apparatus. As shown in the drawing, the spitzkasten has a launder to receive the floating froth which passes away through the outlet. The liquid and the sunken material pass out through the outlet at the bottom of the spitzkasten. The level of the liquid in the spitzkasten is slightly above the lip. Within the spitzkasten is placed an inclined baffle or guide-plate, which may be made adjustable, extending upward from below the inlet and arranged to direct the stream of ore-particles and air-bubbles toward the surface of the liquid in the spitzkasten.

"Hitherto many proposals have been made for the wet concentration of ores involving the addition to the liquid in which the ore is suspended of an immiscible liquid. For example in the patent granted to Cattermole, Sulman & Picard, United States No. 777,274, dated December 13th, 1904, is described a process of ore concentration in which metalliferous particles were coated with a thin film of a fatty or resin acid or a phenol or a cresol by introducing the alkaline compounds of these materials into an acid liquid whereby these materials were liberated in an immiscible or insoluble condition and adhered to the mineral particles. In another known process the powdered ore suspended in water, preferably acidified, is mechanically brought to the surface whereby the particles are exposed to the air and it is found that the metalliferous particles float on the surface while the gangue sinks. In this known process the selective flotation of the metalliferous particles is not due to the metalliferous particles being coated with a selective agent, that is to say, the selective flotation is due to the properties of the metalliferous particles themselves when exposed to air or other gas and brought onto the edge or surface of water preferably acidified.

"The present process differs from the two before mentioned types and from other known concentration processes by the introduction into the acidified ore pulp of a small quantity of a mineral-frothing agent, i. e., an organic compound in solution of the kind above referred to and by the fact that the metalliferous particles are brought to the surface in the form of a froth or scum not by mechanical means, but by the attachment of air or other gas bubbles thereto.

"In the frothing processes hitherto known, the substances used to secure the formation of a mineral-bearing froth has been oil or an oily liquid immiscible with water. According to this invention the mineral-frothing agent consists of an organic compound contained in solution in the acidified water.

"We do not confine ourselves to the proportions above

given; the best proportion can in each case be easily determined by trial.

"It is well known that certain of the organic substances we have referred to are not soluble in water in all proportions and that if used in excess might partly remain insoluble in the acidified water and might become mechanically affixed to the metalliferous particles of the ore. We disclaim any such use of these substances and only claim them in such amount as will enable them to dissolve in the acidified water."

The claims in issue are the following:

"1. The herein described process of concentrating ores which consists in mixing the powdered ore with water containing in solution a small quantity of a mineral-frothing agent, agitating the mixture to form a froth and separating the froth.

"2. The herein described process of concentrating ores, which consists in mixing the powdered ore with water containing in solution a small quantity of an organic mineral-frothing agent, agitating the mixture to form a froth and separating the froth.

"5. The herein described process of concentrating ores which consists in mixing the powdered ore with water containing in solution a small quantity of a mineral-frothing agent, agitating the mixture and beating air into it in a finely divided state so as to form froth and separating the froth.

"6. The herein described process of concentrating ores which consists in mixing the powdered ore with water containing in solution a small quantity of a mineral-frothing agent, agitating the mixture and beating air into it in a finely divided state so as to form froth and separating the froth."

The difference between the two patents may be shortly stated to be this: The first process rests upon the use in very small quantity of an oily substance that does not dissolve in water, coupled with agitation of the pulp, and this succeeds in producing a special froth that is remarkably effective in recovering the minute particles of ore. The second process does not employ oil, or an undissolvable substance; on the contrary, the "mineral-frothing agent" must be in solution, and *ex vi termini* must therefore be dissolvable. The specification disclaims the use of so large a quantity that part of it remains undissolved. The "mineral-frothing agent" is further limited by describing it as "one or more organic substances which enable metallic sulphides to float under conditions hereinafter specified;" and, as this general statement does not convey specific information, the patentees give several examples of organic substances that are found to be suitable for use in solution. In passing, we may note that claims 1 and 5 are broad enough to cover inorganic frothing agents also, but as no such agent is yet known, this feature need not now be considered. Just how or why this solution with the needful agitation produces the froth, is not certainly known; but the fact is, that (to use the language of the brief):

"• • • its effect (is) to produce a similar action of

air bubbles in the attraction of metallic particles, a similar levitation of the metallic particles, a similar persistence of the bubbles, a similar reliable adherence of the air bubbles to the metallic particles, and a similar capacity for final separation of the metallic particles by their overflow, still in attachment to air bubbles, at the top of a vessel containing the pulp."

An observable difference in effect is that the froth of the second patent is composed of bubbles much smaller than the bubbles of the oil process.

We may also note that while the addition of an acid to the mineral-frothing agent is described as part of the process, this was at that time a usual practice, and in any event is not an element in the claims now in issue. The agitation is to be thorough, but in the same connection the means for bringing this about is described in terms that are wide and inclusive. The air or other gas is to be "liberated in, generated in, or effectively introduced into, the mixture," in order that the ore particles may come into contact with the gas and as a result may float to the surface in the form of a froth or scum which can be separated afterward by any well known means. The object of introducing the air or other gas into the mixture is such agitation of the pulp as will produce the desired froth, but the claims are not confined to a particular device or a particular degree of agitation. But, of course, the agitation must be thorough and it must be effective, these being matters for experiment, but always with the ultimate object of bringing the sulphide particles to the surface and holding them there in the grasp of a froth.

We do not find it necessary to discuss the question of validity; our conclusion is, that the patent discloses invention and has not been anticipated. As in the case of the oil process, the patentees seem to have taken "the final step which converted experiment into solution, turned failure into success" (*Minerals Separation Co. v. Hyde*, U. S.,); and we find nothing in the prior art that can be held to anticipate. The real question upon this patent also is the question of infringement, and here as well as there the decision turns upon the kind and degree of agitation employed by the defendant. We need not dwell upon the subject, for as the defendant used both processes conjointly it is evident that what has been said about the infringing agitation in the oil process must also apply to the same agitation when considered in reference to the second process. There is this difference, however: As pointed out above, the agitation of the second process is so described as to cover expressly a wider range of means and degrees than is expressly covered by the first process, and therefore needs less aid, if any, from the doctrine of equivalents. For the reasons given in discussing the oil patent, we think the defendant's practices there described infringe also the process now under consideration.

THIRD PATENT

The third patent involved in this suit, No. 1,099,699—also for improvements in ore concentration—was ap-

plied for on June 30, 1911, was issued on June 9, 1914, to Henry Howard Greenway, and has not been judicially passed upon except by the Court below. As stated in the specification, its process is "a modification of the invention described in U. S. Patent to H. L. Sulman, A. H. Higgins and myself, No. 962,678, granted June 28, 1910," which is the second patent here in suit. Greenway's particular object was "to separate certain constituents of the ore such as copper sulphides (for example in the form of copper pyrites or metallic copper natural or reduced) from other constituents, such as gangue, where the ore is suspended in a liquid such as water." After describing the process of No. 962,678, as one "applicable generally to the recovery of metallic sulphides and like floatable metalliferous matter and in case of lead and zinc sulphides to which the process has been largely applied" and stating that in such process "it is necessary for efficient working that the pulp should be lightly acidified, and in most cases in practice the pulp is heated," the patentee disclosed his discovery, namely, that both acids and heat can be dispensed with, saying that, "It is now found that with copper ore such as an ore containing copper pyrites effective separation is obtained in the cold without the use of acid by employing as mineral-frothing agents, aromatic hydroxy compounds such as phenol, cresol, or mixtures containing the same." Upon this disclosure the claims here in issue were granted, illustrative of which Claim 12 is for "a process of concentrating ores, which consists in mixing a powdered ore containing copper with neutral water containing in solution a minute quantity of cresol, agitating the mixture in the cold to form a froth and separating the froth." In the Court below the patent was held invalid and agreeing, as we do, with the conclusion reached by it in reference to the first and second patents, we are the more inclined to follow its decree in reference to the third patent. But an examination of the proofs satisfies us that the process disclosed in this patent was a substantial departure from processes of the prior art. The heating of water is a matter of large moment in large operations, and the use of acid is a matter of constant and considerable expense. By wholly dispensing with both by the use of a minute quantity of hydroxy compounds, the patentee has disclosed an original and novel plan which has broadened and made more simple the agitation process of air flotation. The length of this opinion, rendered necessary in the full discussion of the first patent, is the sufficient warrant for our refraining from a detailed discussion of the proofs and reasons which lead to our conclusion as to the novelty and inventive character of Greenway's discovery, and we therefore limit ourselves to stating that after full consideration we have reached the conclusion that his patent is valid, and, for the reasons stated in discussing the first patent, is infringed by the defendant.

It is ordered that the part of the decree of the District Court holding valid and infringed Claims 1 and 12, and invalid Claim 9, of Letters Patent No. 835,120, and holding valid and infringed Claims 1, 2, 5 and 6 of Letters

Patent No. 692,678, be affirmed, and that the part holding invalid Claims 1 to 12 of Letters Patent No. 1,099,699, be reversed; and that a decree in accordance with this opinion be entered.

Montana Section of A. I. M. E.

On the evening of May 21, the Montana section held one of its informal dinners at the Silver Bow Club, Butte, Montana. Forty-seven members and ten guests were present. The purpose of the meeting was to welcome President P. N. Moore of the Institute, and to discuss the general topic, 'How Can the Institute Best Serve the Country in the Present Crisis?' After dinner, F. W. Bacorn, the chairman, made a few remarks on the purpose of the meeting and introduced Col. Dan J. Donohue, who ably discussed the problems of the Army. The Navy was reviewed in an interesting way by Eugene Carroll. Discussion followed by E. H. Wilson and B. H. Dunshee. Mr. Moore then spoke on the relation of the Institute to the Council of National Defense. He paid high tribute to H. C. Hoover and his work in Belgium; and closed with an interesting review of the internal problems of the Institute. Discussion followed by J. L. Bruce, C. W. Goodale, James M. Hyde, J. N. Houser of St. Louis, and Oscar Rohn. On May 22, luncheon was served by the Anaconda members of the A. I. M. E. at the Anaconda Country Club, in honor of President Moore. Covers were laid for 56. After the repast, C. D. Demond called the members to order in the reception-hall and introduced the guest of honor. Mr. Moore contributed anecdotes, advice, and information, all of which were appreciated greatly by all the young men present.

NORMAL requirements of platinum in the United States call for 165,000 oz. per year, part of which is supplied by refining scrap and sweeps. The dental industry formerly used between 25 and 30% of the supply, part of which is not recoverable. Dental manufacturers are now using a number of alloys in place of platinum. The jewelry industry uses between 40 and 50% of the supply, practically all of which would be recoverable if necessity should arise. In 1915 about 44,000 oz., or 4% of the apparent United States stock of platinum, was used in contact-process sulphuric-acid works, producing strong acid for munition makers. The output of contact-process plants has increased nearly 200% since 1915, and it is understood that plants using this process are not yet operated to their full capacity, accordingly there is no pressing need for a large supply of platinum by the sulphuric-acid industry. The government laboratories are apparently well supplied with platinum utensils, and are not in the market for platinum at present, except as investigations on a larger scale may require new equipment. The U. S. mints refine platinum and doubtless have stocks sufficient to meet immediate governmental requirements.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

PLATTEVILLE, WISCONSIN

A SHORTAGE OF LABOR RESTRICTS OUTPUT SOMEWHAT.—NEW PLANTS BEING BUILT AND OTHERS PLANNED.—HIGH PRICES STIMULATE LESSEES THROUGHOUT THE FIELD.

Intensified activity for about two years or more, in both exploration and development work, has given to the Wisconsin zinc-field a present normal out-putting capacity of not less than 6000 short tons of concentrate weekly. Complete returns from all active mining districts for May, show a complete recovery of little more than 18,000 tons crude concentrate, a rather disappointing output, since the weather-man was prejudiced in favor of the miner throughout the month. Prices for zinc ore for the month were fair on standard and premium-grades, opening the first week in the month at \$72.50 base, with the range down to \$65; advances were gradual to the end of the month, the second week's quotations going to \$75 per ton for top, and \$68 for medium and second-grades; third week, \$77.50 with the range down to \$70; and the remainder of the month at \$78 base, with the range narrowed on inferior grades down to \$72. Apparently there appeared to be a well-defined policy on the part of high-grade producers and refiners to restrict both output and deliveries. A careful investigation in the second half of the month revealed the real cause for the slump in output. Nearly every village and city and mining-camp in the field was sending more than its lawful quota of fighting-men into the training-camps. Platteville alone sent 168 men, all hand-picked brawny, intelligent, brave men, most of whom came from the mines. Added to the enthusiastic enlistments came another disturbing factor in the working-forces employed in the mines. Many farmers and farm-help flock to the mines each autumn after the harvests, returning to till the soil during the summer season. Cold weather lingering in the lap of spring this year delayed this exodus until well along in the month of May when hundreds left the mines.

Leading operators all over the field were scouring the country for additional labor, which it is found most difficult to replace. One of the more prominent operators declared he could use 200 men and offered a bonus for ready help. To add to this came new embarrassments. There were sharp advances in the price of explosives, approximating 12½%. Likewise in mill-supplies, which tended to offset the higher price of zinc ore. Yet, with all the obstacles placed in the way of operators, May was a period of excellent profit-taking. More high-grade ore proportionately to the output left the field than usual. Refiners all ran at maximum capacity and the associated mines contributed as well as depleted working-forces would allow. Preparations were made for a comprehensive tabulation of expense, which will show the cost of ore production based on the present price of supplies and labor. Several new mines came into production during the month, but in nearly every instance superintendents and mine-managers admitted that the lack of labor was responsible for both restricted output from the mines and the recovery of concentrate from mills. This situation is discouraging prospect-work, and mine development is gradually becoming less pronounced. The New Jersey Zinc Co., for ten years or more one of the most active corporations in the region for the production of zinc ore, is not engaged in mine development anywhere in the field and has no drill-squads at work anywhere on untried ground. In

fact, reference to the daily car-reports issued for the mines shows that deliveries of zinc concentrate to the company's refineries at Mineral Point have fallen off from 10 to 15 cars, weekly. Each of the company's mines shows a reduction in the tonnage mined, mainly due, however, to disorganized conditions in several classes of mine employment.

Delegates of the I. W. W. contributed to the discomfort of mine-operators by engaging the attention of miners in the southern districts of the field, where open-air meetings were held and a 5-hour working day was advocated with pay for the usual 9 and 10-hour day. To the credit of the men employed in the zinc mines no chapters were organized and there was no evidence that an impression had been made upon them. Wisconsin zinc miners are a well-paid class of men at this time, as has been pointed out by the publication of the wage-schedule in previous issues of the MINING & SCIENTIFIC PRESS. It will be found upon investigation also that every possible care and comfort is being shown the men. Club and reading-rooms, libraries, baths, gymnasiums, and other modern conveniences are being supplied the men near the scene of their labors in buildings especially constructed and provided for their comfort, amusement, and benefit. Several companies set aside large tracts of land and donated thousands of dollars worth of seed-potatoes cutting out working-time to enable their many employees to prepare their allotments of land for planting. It is hard to conceive how any class of men can fail to appreciate the indulgent attitude of the mine operators of Wisconsin. Nearly every company of note in the field has built cottages for men of families, which are occupied free of charge.

That every cloud has its silver lining was illustrated during May in the operations of lead-ore producers, keen-scented individuals on the selling-side of the market when the figures chalked-up on the score-board look nearly right. Real competition developed in this quarter during the month. The Eagle-Picher Lead Co. abandoned the leased smelter at Collinsville, Illinois, and instructed its buyers in the Wisconsin field to buy lead ore. Prior to this move, the New Jersey Zinc Co., which had confined its operations to the buying and production of zinc ore, also placed a buyer in the field, and the price jumped from about \$110 per ton, at the beginning of the month to \$125 per ton, the second week, and held at this figure the remainder of the month, while the best offerings published for the Joplin field held at about \$120. Conservative estimates on the tonnage held in the field May 1, was 1200 to 1500 tons. While reports are given out weekly on the total recoveries of zinc ore at mines, no such procedure is seen concerning lead ore. An increased output of zinc ore warrants a larger recovery of lead ore in the Wisconsin field, as most of the lead ore is secured as a by-product in concentration. Sales and shipments jumped from one or two cars weekly to 8 and 10 cars, and a fair tonnage was marketed, but the sold-up condition of the pig-lead market encouraged lead-ore producers into the belief that still better prices were in store for them, and not all the lead ore was sent to the railroad. While not in such pronounced degree as indicated regarding loss of men from mine pay-rolls, nevertheless many miners invaded shallow diggings during the month in the hope that gophering for lead ore would prove more remunerative than the wage at the mines.

The production of iron pyrite during the month was more than ever confined to recoveries made at magnetic ore-sep-

arating plants in the field. The manufacture of sulphuric acid was stimulated at both Mineral Point and DePue, Illinois, where 66° acid is manufactured. Prices for pyrite remained stagnant. In fact it is almost next to impossible to get any of the producers to reveal the prices now being obtained, but that these prices are not satisfactory was admitted by two reliable producers. One large refiner stated that the unrestricted submarine warfare has greatly lessened, if not entirely prohibited, the import of pyrite, and that before long acid manufacturers most likely will make better offers to American producers of iron pyrite and other sulphur ores. Shipments were exceedingly light all month and a careful estimate of ore now held by refiners shows it to be several thousand tons.

Producers of carbonate zinc ore in the northern districts found offerings for this class of ore at sad variance with the quotations published for similar ores in the Joplin region where the price ranged most of the month from \$40 to \$50 per ton, base of 40% zinc assays. Output was increased appreciably by the introduction of two new mines operated by the New Jersey Zinc Co. and several small local operating concerns that are carrying a small tonnage in the hope of a better demand.

Low-grade blende producers found markets unsuited to a normal output and shipments fell under the usual tonnage reported from this source. The only outlet afforded low-grade producers of large output was the Mineral Point Zinc Company.

Shipments of zinc ore, lead ore, and pyrite for May from mines to refiners and to smelters were as follows:

Districts	Mine-run zinc ore, lb.	Lead, lb.	Pyrite, lb.
Benton	16,480,000	410,000
Mifflin	5,704,000	286,000
Galena	2,614,000	68,000
Linden	2,608,000	142,000
Hazel Green	1,920,000	80,000
Shullsburg	1,012,000	66,000
Platteville	950,000	168,000
Highland	480,000	120,000
Potosi	480,000	111,000
Mineral Point	144,000	1,742,000
Montfort	242,000	50,000
Cuba City	90,000	2,704,000
Total	32,724,000	1,359,000	4,588,000

Shipments of high-grade refinery-ore for the month were made as shown: Benton, 4,854,000 lb.; Cuba City, 3,128,000 lb.; Mineral Point, 4,270,000 lb.; Shullsburg, 348,000 lb.; Linden, 338,000 lb.; total, 12,938,000 pounds.

On account of the falling off in receipts of low-grade ore at Mineral Point a corresponding decrease is shown in the marketing of high-grade separator-ore.

The total net deliveries of zinc ore out of the field for May aggregated 10,792 tons, including the period from May 1 to May 26, inclusive. Of this amount the Grasselli Chemical Co. of Cleveland, Ohio, received 3322 tons; American Zinc Co., of Hillsboro, Illinois, 2548 tons; Mineral Point Zinc Co., DePue, Illinois, 2135 tons; Edgar Zinc Co., 690 tons; Matthiesen & Hegeler Zinc Co., LaSalle, Illinois, 629 tons; Illinois Zinc Co., Peru, Illinois, 487 tons; American Metals Co., Langeloth, Pennsylvania, 461 tons; Lanyon Zinc Co., East St. Louis, Illinois, 280 tons; Highland mines to smelter direct, 240 tons.

Fair weather brought out a diversity of accomplishments in the many mining districts of the field. Highland reported the introduction of two new mills and producers—the new Kennedy-Eberle mine and the Red-Jacket mine; Montfort was excited over a rich strike of zinc ore west of the old workings on the O. P. David tract where Theo. A. Waech, the superintendent, surveyed a new run of ore and the drills showed 8 ft.

of solid zinc ore, assays from 121 to 129 ft. running 30% of ore in the rock. Adjoining lands were quickly taken for prospecting purposes; the Linden camp showed wonderful strikes of zinc ore on the Treloar-Kickapoo leases owned by the Saxe-Pollard company, where two new shafts were started one-half mile apart. A new 200-ton power and concentrating-plant will be erected mid-way between the two mines, which will operate both mines and mills. The Utt-Thorne Mining Co. took over the Harris mine and mill at Mineral Point, changing the name to the McIlhon mine and will operate three leases in combination through the central plant. The Dodgeville district reported the completion of a new 150-ton mill on the Berryman farm, for the North Survey Mining Co., operations to begin not later than June 10. The Mifflin district reported two dividend payers, the Big Tom and Peacock mines, both of good reputation in this respect. A considerable tonnage of zinc ore was carried over at this point. The Platteville district failed to show much in the way of production during May, but several new producers got into action—the Mann & Harding mine, New Rose Mining Co., and New Empire Mining Co. The Block-House Mining Co. reaped fair profits on sales of lead ore, carried over \$100,000 worth of high-grade refined zinc ore, and paid a dividend of 100%, the third so far this year. The Wisconsin Zinc Co. paid a quarterly dividend of 2%, the fifth, on stock of record May 21, and A. W. Plumb, of Denver, Colorado, succeeded H. C. George as general manager of the company. Drilling outfits discovered extensive deposits of zinc ore on the Weigle tract of 113 acres for the Block-House Mining Co., the title being vested in the operator. Cuba City, the home of two well-established zinc-ore refineries, turned in a fair tonnage of high-grade material not all of which was sent to market, several hundred tons of high-grade being carried over. The Singer-Campbell suffered the loss of one wing of the plant through fire. It is to be replaced without delay. The Utt-Thorne Mining Co. developed ore in quantity on the G. O. P. lease, and building-material and machinery was being assembled for a new plant at the close of the month. Benton district made heavy deliveries of raw ore to refiners and smelters. Especially noteworthy was the performance of both the Frontier and Wisconsin Zinc Co.'s group of mines, the former shipping as high as 27 cars of concentrate in a single week, and from May 1 to May 26, 3457 tons. The aim of the management is to turn in 1000 tons of concentrate weekly and new producers are contributing admirably, especially the Middle mine, a new producer. In the same period the Wisconsin Zinc Co. turned in to its separators at New Diggings 3540 tons of raw ore from which was recovered 2129 tons of 60% blende, sold to the American, Lanyon, and Edgar Zinc companies.

The Longhorn mine, a recent addition to the Wisconsin Zinc Co.'s producers, yielded as high as 10 and 12 cars of mine-run ore weekly. A new mine has been developed for the Wisconsin Zinc Co. on the Copeland estate, in the Shullsburg district, which is now being supplied with a modern mining and milling surface-plant. The Vinegar Hill Zinc Co. introduced a new producer with surface-rig complete. It is known as the Meloy mine. Another producer will be developed for the company on what is known as the New York lease, now being explored with drills. The Felds Mining & Milling Co. made a fair record with one producer, the Thompson mine, shipping, under contract, 23 cars of ore during the month from this one producer to the Grasselli Chemical Co. The New Jersey Zinc Co., on the Fox and Penna-Benton mines, did not report as well as has been the custom. A comparison of mine-run output made in the Benton district with that made by the entire field for the 26 days reported in May reveals the fact that better than one-half of the raw ore mined in the field is coming from this section; the count being 253 out of a possible 452 cars. The Strawbridge Mining Co. of Milwaukee, George E. Orput, formerly of Platteville, manager, was well along with a new 150-ton power, mining, and milling-plant. Ex-

tensive deposits of zinc ore have been proved with drills. The building of a branch railway into the New Diggings camp has inspired new life on all sides, the village experiencing a building boom. In the Shullsburg camp production was revived by the Wisconsin Zinc Co. on a large scale at the Win-skill mine. The Oliver Mining Co. continued its large output of refined raw ore, but made light shipments, holding the finished produce for better prices. The Rodhams-McQuitty Mining Co. followed the same programme, carrying over both lead and zinc ore in quantity. The Rowe Mining Co. restored the Milwaukee-Shullsburg mine, installing heavy cross-head pumps.

TORONTO, CANADA

IN ALBERTA 6000 COAL MINERS STRIKE.—EFFECT ON METAL MINES AND MUNITIONS MANUFACTURE.—INCREASED SHIPPING TONNAGE NECESSARY.

The dissatisfaction which has prevailed for some time among the coal miners of Alberta and eastern British Columbia, and who have been demanding an increase of 25% in wages, has resulted in the calling of a strike by the officials of district No. 18, United Mine Workers of America, the headquarters of which is at Calgary. This action affects 6000 miners, the majority of whom, however, had ceased work on their own initiative some weeks before the strike was officially authorized by the union on May 14. This action is seriously affecting the metallurgical industries of British Columbia, as the smelters receive their supplies of coke from the ovens of the Crow's Nest Pass area, which have had to close down by reason of the strike. The smelter of the Granby Consolidated Mining & Smelting Co. at Grand Forks, B. C., has suspended operations, and the closing of the Canadian Consolidated Mining & Smelting Company's plant, at Trill, is anticipated unless the situation improves. As the Granby smelter is the principal producer of copper in western Canada its suspension may considerably curtail the manufacture of munitions in the plants of eastern Canada, which are largely supplied from this source. The Canadian Labor Department has proposed the usual remedy, a Royal Commission of inquiry, but so far the coal-miners are not disposed to listen to any suggestion of compromise, and apparently consider themselves able to dictate terms to the mine operators.

The munition-manufacturing industry has slackened off greatly from other causes, the principal one of which is the completion of large contracts without a renewal of orders. It is officially stated by J. W. Flavell, chairman of the Imperial Munitions Board, that development in the British Munition plants has reached a point which will render it unnecessary to place further orders for the larger sizes of shells in Canada, but that contracts for the small shells will continue to be placed. Some of the manufacturers, moreover, consider the terms of the later contracts too exacting, and are giving up munition-making. In Toronto operations have been greatly curtailed, and many munition workers discharged. The Fairbanks Morse Co. (Ltd.), one of the largest firms in the trade, has laid off 1100 men and women in this department, and is only running a day-shift in place of full 24 hours.

With the decrease of the demand for shells which bids fair to be permanent, the opportunity for the expansion of the steel-shipbuilding industry has greatly improved. A few weeks since an extensive programme for the building up of this industry was receiving the consideration of the Government, and a number of capitalists. The principal drawback to speedy action was found to be the difficulty of procuring steel. Mark Workman, president of the Dominion Steel Corporation, of Sydney, N. S., recently stated that the entire output of its plant had been contracted for by the Imperial Munitions Board for shell-making up to the middle of 1918, and that in consequence they could do nothing to supply the urgent de-

mand of the railway companies for steel rails. Arrangements are now being made to secure from the Munitions Board a release of the steel necessary for the rails required for renewals on the Government railways. As an increase in shipping tonnage appears to be more urgently required by the Imperial Government than further supplies of munitions, it appears altogether probable that a part of the larger quantities of steel contracted for by the Imperial Munitions Board may be devoted to this purpose. Preparations for securing an ample supply of raw material for the shipbuilding industry are being energetically pushed. The large steel works of the British Forgings (Ltd.) at Toronto, are being hurried to completion and are expected to be in operation about the end of June. The project of the United States Steel Corporation for a Canadian plant on the Detroit river, near Windsor, which had been in contemplation for some years, but was indefinitely postponed owing to the outbreak of the War, has been revived and \$9,000,000 appropriated for construction, a site of several hundred acres having been secured. The first unit will be devoted to ship-plates and shapes.

COBALT, ONTARIO

PROBABLE CANCELLATION OF ANNUAL LABOR ON MINING CLAIMS BY THE GOVERNMENT.—OLD HARGRAVES MINE RE-OPENED.—STRIKERS SEEK CONFERENCE.

It is likely that all mining claims in Ontario, recorded prior to April 1917, will be exempt from the compulsory performance of assessment work. Throughout northern Ontario there are at least 3000 claims upon which assessment work will fall due before the end of the current year. Ontario mining claims are obtained by discovery and the performance of assessment-work within 30 days after discovery, 60 days the first year, 60 days the second year, and 90 days the third year. Provided there are 3000 claims on which the amount of work due this year averages 60 days, it follows that 180,000 days of work must be performed in order to keep all in good standing. This would require approximately 600 men working steadily for one year. The energy thus released by the omission of assessment-work would tend to greatly improve the labor supply at the producing mines of this district.

Captain Joergensen, of London, England, president of the Cobalt Aladdin Mining Co., formerly the Chambers-Ferland, is in Canada attending the annual meeting of the company at Cobalt. He has been with his regiment in France since the fall of 1914, and is now on leave for one month.

The Hargraves mine, after being closed for the past four years, was re-opened a few months ago, and made its first car-load shipment of high-grade ore this month. The Prince David mine, lying immediately west of the Beaver and Temiskaming mines, has started exploration by a cross-cut from the lower level of the neighboring Lumsden shaft.

The local miners union which is affiliated with the International Mine & Smelter Workers Union, has made demands on the mines at Porcupine, Kirkland Lake, Boston Creek, Gowganda, and Cobalt, and has asked for a conference with the several managers before the end of the month. In the past there has been no tendency on the part of the mine managers to recognize this union nor is there likely to be now. The miners at the Cobalt camp receive the same wages as that asked for by the union, but receive 50c. per shift of this wage in the form of a bonus, based on the price of silver at 70c. Drill-runners at Cobalt receive \$4 for an eight-hour shift.

From Porcupine and Cobalt there is now coming a constant stream of silver and gold, amounting to approximately \$75,000 per day, Sunday's included; over \$27,000,000 per annum. That the industry should be allowed to suffer from a lack of workers is a growing puzzle to not a few mining men of this district, for from present indications, the resources of northern Ontario have not yet reached anything like the limit of expansion.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

(Special Correspondence.)—Fred Laubner has taken a contract to drive 500 ft. on a vein for the Gold Cord Mining Co. at Knick. The company has leased the mill of the Independence Mining Co. on Willow creek.—The Wallace Mining & Milling Co. is running a 400-ft. cross-cut.—Fern and Goodell are driving an adit on a 12-ft. vein, the ore running \$5 per ton in gold.

The Free Gold Mining & Milling Co.'s plant will start May 21. There is now ready for the mill 500 tons of ore. The Susitna river is still frozen but the ice is expected to break up any day.

Anchorage, May 20.

JUNEAU

The London *Financial Times* prints the following telegram from F. W. Bradley, president of the Alaska Treadwell Companies:

"A subsidence on the line of the fault-plane hopelessly flooded the workings of the Alaska Treadwell, 700 ft., and the Alaska Mexican mines, but the Ready Bullion mine (belonging to the Alaska United Company) is considered safe. The operation of the Ready Bullion mine, together with commercial operations in connection with the store, the foundry, power and cyanide-plant, and other joint utilities owned by the three companies should yield small earnings for each one of them. There is a hope that eventually a future deep level from the Ready Bullion mine may prospect the Treadwell ore-shoot below the flooded workings. The Consolidation scheme must be held in abeyance and no further expense must be incurred, as the proposed basis is impracticable.

PRINCE OF WALES ISLAND

(Special Correspondence.)—The Mount Andrew mine is located a mile from the beach at Kasaan bay, and is owned by the Mt. Andrew Mining Co. It is being operated at present by W. J. Rodgers. Mining was commenced on April 1 of this year. Ore shipped during May amounted to 750 tons. The shipment during June will reach 900 tons. The ore is delivered to the bunkers at the beach by a 4600-ft. Riblett tramway, and is taken from there by boat to the Granby smelter at Anyox. B. C. The orebodies are large and consist of magnetite and chalcopryite. Irregular lenses of higher grade chalcopryite ore are found within the main orebody, and are being mined by glory-hole and other surface methods. The ore shipped to the smelter, after rough sorting in the mine, returns 5% copper and 80c. in gold. Twenty-five men are employed and the mine is worked eight months of the year.

The It mine, owned by the Granby company, is breaking 50 tons of rough-sorted ore daily that averages 5% copper. Fifty men are employed there. The bunk and mess-houses are being enlarged to accommodate a larger number of men.

The Mamie mine, also owned by the Granby company, is closed down. Extensive development has been done on this property during the past three years, and it reached a capacity of 200 tons of shipping-ore per day at one time within that period. It is a fully equipped property and is probably closed temporarily.

Notwithstanding the large number of men that were thrown out of employment by the disaster at the Treadwell mines, there is a labor shortage all along the south-eastern coast of Alaska.

Prince of Wales Island, June 1.

ARIZONA

GILA COUNTY

(Special Correspondence.)—A strike of good sulphide ore was made lately in the New Dominion mine at Globe. The vein was found on the 800-ft. level in cross-cutting 60 ft. south of the old Mallory shaft and has widened from 3½ to nearly 7 ft. in driving 20 ft. Shipments from this orebody to the Old Dominion smelter, 1½ miles by road, have averaged close to 8%, according to reports. Recently the old cross-cut to the north has been cleaned out and driving will be continued from the point where operations were suspended about 10 years ago. This was one of the properties which was there, before the panic of 1907, under development by the Globe Consolidated and in which difficulties were met in unwatering the mine. Since then the adjoining workings of the Old Dominion have been considerably deepened so that now the draining of the New Dominion is probably affected by its neighbor to the south. Whatever the cause, the 800-ft. level of the New Dominion is dry, and the shaft may be sunk from 300 to 400 ft. deeper before pumping will be necessary, as the Old Dominion workings are down 1800 feet.

Globe, May 31.

YAVAPAI COUNTY

(Special Correspondence.)—The Arizona Binghamton Copper Co., at Stoddard, is the successor to the Stoddard Mines Company and has developed a large body of chalcopryite and tetrahedrite, which averages 15% copper, on the 400-ft. level. This orebody has been developed on the upper levels and is being cross-cut for on the 600-ft. level. This company now owns the Stoddard Milling Co., which plant will be increased from 100 tons to 250 tons per day by the first part of June. May copper production will be about 300,000 lb. Ore treated is running over 5% copper.

Stoddard, May 31.

MOHAVE COUNTY

(Special Correspondence.)—The new custom mill at Chloride is expected to be completed by June 15. There is a large amount of ore available to keep the mill steadily occupied and a large output for this promising district is anticipated. Not less than 50 mines are being developed as rapidly as the resources of the owner and lessees will permit, and Chloride is at last about to enter on an era of prosperity long delayed, but none the less assured.

Chloride, June 8.

CALIFORNIA

Reports filed with the State Mining Bureau for the week ended June 2, 1917, show eight new wells started, making a total of 479 since the first of the year; 31 wells were ready for test of water shut-off, 15 deepening or re-drilling and 6 abandoned. The amendments to the law providing for protecting Californian oil fields from damage by infiltrating water have been signed by Governor Stephens and become effective July 28. The amended law will be distributed to all operators at an early date. The changes are of vital importance in meeting the demands caused by the present oil-field activities which are far beyond those of two years ago when the State law was first passed. One of the most important changes provides for local boards of commissioners to be elected by the oil-operators, or land owners, who pay assessments under the law regulating the drilling of wells. The boards of commissioners

replace the special arbitration boards previously provided for, in the law, and also have certain duties in conjunction with the State oil and gas supervisor.

ELDORADO COUNTY

(Special Correspondence.)—The Eldorado Exploration Company of Tacoma is developing a property on the Mother Lode, about 8 miles south of Placerville, and about half way between the Montezuma mine, near Nashville, and the Springfield mine. The company has been working on the property during the past year and expects soon to build a mill of 50 tons capacity. There are two veins in the property, several hundred feet apart. Good ore has been discovered at three places and it is the development of these shoots that is now being undertaken. John W. Cover is general manager.

Placerville, June 4.

SIERRA COUNTY

(Special Correspondence.)—Sinking of the 200-ft. shaft at the Mariposa is proceeding 100 ft. deeper, from which point a cross-cut will be driven to the vein. An Ingersoll-Rand compressor, operated by a 150-hp. motor, has been installed, and arrangements have been made for the addition of five stamps to the 5-stamp mill. The property was recently inspected by Nathan Haessly, the president of the company.

Much new work is going on at the Morning Glory, adjoining the Tightner. The shaft is down 130 ft. and will be continued to a depth of 300 ft. Orders will be placed shortly for a pump and other equipment. The mill is running on ore of good grade. The vein averages 4 ft. wide. A. A. Codd, of Reno, Nevada, is manager.

Driving has started from the 100-ft. level of the York-Finney mine, near Downieville, to open the main ore-shoot. As soon as this is done a south drift will be extended to prospect an unexplored part of the property. Rich ore was mined near the surface 20 years ago.

Work has been resumed recently on a number of quartz properties in the Downieville district. At the Alhambra, Rixey and Spornhill are opening the vein with drifts and exposing some good quartz. Preliminary work has begun at the Snow Point, with George Hegarty in charge. Work is proceeding at the Kirkpatrick, near Mountain House, with encouraging results. V. G. Helmet is superintendent.

Good and Hussey are developing a promising quartz property at Bassett Station, a few miles from Beckwith, and have started the erection of a small testing-plant. The ore contains gold, silver, and copper, with the vein several feet wide. The plant will be electrically operated, current being supplied from a small generating-plant at the mine.

Alleghany, June 6.

TRINITY COUNTY

(Special Correspondence.)—Convinced after months of experiments and determined effort that dredging of the rich placers in Morrison gulch is impracticable, the Pacific Gold Dredging Co. has arranged to dismantle No. 1 dredge and move it four miles down Coffee creek to a point near the Trinity river, where the ground is ideal for dredging. This steel dredge cost approximately \$400,000. It is constructed to dig in exceptionally difficult ground. The Morrison gulch deposit is stated to carry a high gold content, but the presence of numerous large boulders constantly ripped off the manganese-steel lips of the buckets, despite the use of every precaution. It is reported the company will begin construction of No. 2 dredge at an early date. Meanwhile prospecting of wide areas of promising ground with drills continues.

The Trinity Star Dredging Co. has excavated a pit for the dredge to be operated on the Trinity river, near Lewiston. Unlike most modern dredges, the hull is to be of wood. Lumber is already delivered and machinery is being shipped from Redding. It is stated the ground can be easily dredged.

Considerable work is going forward at the Jubilee and Poeth mines, controlled by the California Extraction Co., of San

Francisco. Much good ore has been blocked out and the mill is being improved to effect a satisfactory gold extraction from the sulphide ore, which increases with depth. It is reported that the company plans extensive work at the Headlight mine, which at one time was a good producer.

Carrville, June 4.

TULARE COUNTY

(Special Correspondence.)—The Porterville Magnesite Co., the largest organization mining magnesite in this district, is installing two large electric-motors at their foot-hill plant near Porterville, one of 100, the other of 50 hp. The larger motor will be used to operate the compressor-plant which furnishes air for the seven machine-drills used in mining the ore. These motors replace the gas-engine formerly in use. The smaller motor will operate a new ore-crusher. The new installation of machinery will add materially to the efficiency of the plant, and with the other electric-driven machinery of the plant will consume 330 hp., making this company the largest single user of electric power in the county. The 125-ft. rotary kiln recently installed at the plant is calcining about 200 tons of ore daily.

The California Talc & Soapstone Corporation recently began the mining of talc near Porterville, and is getting out from 4 to 5 tons per day, which is trucked to their grinding-mill at Lindsay. They find a ready market for the talc among the manufacturers of San Francisco and the bay district. It is used principally by manufacturers of soap, fireproof-paint, and rubber.

Porterville, June 8.

COLORADO

TELLER COUNTY

(Special Correspondence.)—Hahnwald, Olsen, and associates, owners of the Queen Bess mine on Tenderfoot hill, working through the 6th level of the Mollie Kathleen shaft, are shipping a 30-ton car of ore per week estimated to average 2 oz. gold to the ton.

Louis Noble has been retained by the Modoc Mines Co. in the capacity of consulting engineer, and the deeper development of the Modoc Battle Mountain mines will be under his direction. Mr. Noble has been engaged in a similar capacity for the Cresson Consolidated Gold Mining & Milling Co., directing new development work. Richard Roloefs, superintendent of the Cresson Con. mine was elected a director of the Modoc Corporation at the last meeting of the company.

The Shoo Fly lease on the Stratton estates Womack hill properties, owned by Aleck Hickman, is producing regularly and making an occasional high-grade shipment. Last week Hickman sacked ore for shipment that assayed 479 oz. to the ton.

Whittenberger and Collins, leasing the Tornado mine of the Elkton Consolidated Gold Mining Co., have loaded out by team their initial shipment, with the expectation of bringing this old producer back to the permanent shipping-list.

Four units of the new Independence mill of the Portland Gold Mining Co. are in operation and treating 1000 tons of low-grade ore daily. The Victor Battle Mountain mill is also handling 500 to 600 tons daily of the lower-grade ores, while all ores of lessees and that mined on company account that runs \$10 to \$12 per ton, is shipped to the Colorado Springs mill. Extensive plans are under way to mine the large low-grade orebodies for treatment at the Independence mill, which is planned to have an ultimate capacity of 1500 tons daily.

Cripple Creek, June 4.

IDAHO

SHOSHONE COUNTY

The Stanley mine is shipping antimony ore rich in gold, says the Wallace Miner. Several years ago the Stanley made shipments of profitable ore, when antimony commanded a lower price than now. The property then passed to the Her-

cules company, and little has since been done toward development until lately. The main working-adit of the Hercules mine, known as the Hummingbird tunnel, passes through the Stanley claim. It is reported that the ore recently shipped came from a drift on the Stanley vein run from the Hummingbird adit.

W. J. Smith, of the Dreadnaught mine, reports 3½ ft. of ore carrying a good grade of lead, zinc, and copper, in a drift run on vein No. 1 from the main cross-cut. Most of the ore is of shipping-grade. There is also 3 ft. of ore of milling-grade exposed. The new development is at a depth of 750 ft. The vein has been opened by cuts and small holes for 1400 ft. along the surface. The mine is on Beaver creek and joins the Toughnut.

MICHIGAN

HOUGHTON COUNTY

The Calumet & Hecla company for itself and subsidiary companies, has subscribed for \$1,250,000 of the Liberty Loan bonds.

MISSOURI

JASPER COUNTY

Over 500 tons of zinc ore was shipped from the Galena district, the last week in May, an increase of 50 tons over the shipment of the previous week. The Black Hills Mining Co. in the same period shipped nearly 100 tons, and the Wayland company 69 tons.

The Wireck 300-ton mill at Tar river has been sold to F. Childress and associates, of Galena, for \$250,000, says the *Joplin Globe*. The mill is half a mile south of Tar river near the Bethel mine. Ore was found in the Wireck mine at 240 ft. and a good grade of concentrate was made in the mill. Several mines near the Wireck are said to have large bodies of good ore, among them the Croesus.

MONTANA

FERGUS COUNTY

(Special Correspondence.)—The Judith Mountain Mining Association has been formed at Maiden to promote the legitimate mining industry in Fergus county. E. B. Coolidge is president, George Wieglanda vice-president, William Young treasurer, H. J. Mantell secretary, J. L. Stuart, John Alexander, George Wieglanda, and E. B. Coolidge are directors.

The heavy snows of winter have been succeeded by the spring rains that have left roads in a very poor condition. Hauling of heavy machinery, coal, and ore to Maiden is not yet possible so only development work can be done there. A large pump will be installed at the Cumberland as soon as the roads permit.

The foundation is in for a new cyanide-plant of 125 tons daily capacity at Giltedge, in the Judith mountains. There are many thousands of tons of tailing of low value in gold, but sufficient to make their re-working profitable. There is in addition a large amount of 'black ore' that was not amenable to the cyanide-process in the nineties, but which the present lessees believe they can work at a profit. A campaign of development will be started in a search for additional ore-bodies.

Vincent Gies has commenced work on the Red Metal group of claims in the Cone Butte district and reports ore of good value in copper, silver, and gold.

It is proving difficult to secure an adequate supply of labor at the Barnes-King mine, at Kendall, in the North Moccasins. Only 65 men are employed instead of the customary 100. Production, however, is improving. The old Kendall mine is being worked by lessees in a small way. Cross-cutting from the adit is in progress at the North Kendall and it is hoped that a better grade of ore will be found.

The miners in the Little Rocky Mountains, in Phillips county, struck recently for a raise in pay. About 225 men

were affected. The Ruby Gulch, Beaver Creek, and August mining companies mines were closed temporarily. They are located at Landusky and Zortman. Later reports say that the men were granted \$4 per day, instead of \$3.50, and have returned to work.

Lewistown, June 4.

SILVERBOW COUNTY

A fire was started, it is reported, by the flame of a carbide-lamp igniting a frayed insulation of an electric wire, on the 2400-ft. level of the Speculator mine, on Anaconda hill at Butte, on Saturday. The fire communicated to the mine-timbers, and spread rapidly. Soon the Granite Mountain shaft, an up-cast, with which the Speculator workings are connected, was a roaring chimney of flame. A large number of men were in the mine at the time, but despite the heroic efforts at rescue many lives were lost. A tool-boy, Manus Dugan, aged 20, directed a party of 27 men, who, including himself, retired into a drift and built a bulk-head to keep out the deadly gases. After remaining imprisoned for 36 hours in the drift until nearly exhausted from lack of oxygen, young Dugan ordered the men to break down the bulk-head and make a dash for the shaft. All of this party were rescued alive except J. H. Adams and Manus Dugan, whose whereabouts was unknown. Rescue-crews made every effort to reach and save the miners in various parts of the mine, and numerous lives were thus saved, but many others, it is feared, were suffocated by the carbon di-oxide that penetrated to every open-place in the mine workings.

NEVADA

CHURCHILL COUNTY

The Nevada Hills Mining Co., of Fairview, has declared a dividend of five cents per share payable on July 1 to stockholders on record June 20. The total disbursement will amount to about \$35,000. The property has been producing for over nine years.

CLARK COUNTY

The lower adit at the Boss mine has reached the vein, 400 ft. below the upper workings. The ore is described as containing lead, gold, and platinum. A test run is being made in the mill and the recovery is stated to be satisfactory, but a change is to be made in the roasting-furnaces so that the heat of the petroleum-burner may be under better control. Heretofore the heat has varied greatly.

The new strike on the 700-ft. level of the Yellow Pine mine, near Good Springs, is said to be of greater importance than was at first supposed. During the past week, says the *Good Springs Gazette*, the drift has been driven through 20 ft. of solid high-grade ore. The dimensions of the orebody are unknown. The strike was made in untried ground that lies beyond a fault that had displaced the orebody mined above and from there downward.

The Contact mine, near Good Springs, is reported to have cut a 5-ft. vein of zinc ore a few days ago and development is being urged, and arrangements made to send out a shipment as soon as possible.

EUREKA COUNTY

(Special Correspondence.)—Owing to not being able to get distillate for their hoisting-engine and compressor, the Connelly mine had to shut down, and there is no assurance of getting any for 30 days. The Connelly is being operated by Major Catlin and had from 12 to 15 men on the pay-roll, in charge of Julius Heubner, who has been driving on the 400-ft. level to open-up proved orebodies. As soon as the new electric power-plant at Eureka is in operation, a power-line 4½ miles long will be constructed and sinking to the 1000-ft. level will be continued.

Tony Romana is sorting and shipping matte from the Silver West slag dump, and also has several men jiggling the fine. This the present prices of metals allows them to do at a

handsome profit as the ore was only partly smelted in the early days when fluxing was little understood.

The Ruby Hill tunnel, 2000 ft. long, is being cleared out for an examination of the workings driven out from it. This work is done pending a sale of the property.

Eureka, June 3.

HUMBOLDT COUNTY

(Special Correspondence.)—An auto stage-line has been placed in operation between Lovelock, Rochester, Oreana, and Packard, greatly improving passenger service between those places and the railroad. Considerable building activity is evident in both Rochester and Packard, and the outlook is favorable for a busy summer, particularly in the Rochester field. The Rochester Combined company has completed the 4-in. pipe-line from springs in Rochester canyon to the mill-site, and has started building of mine and office structures. Construction of the mill will start soon. Mine conditions are satisfactory. The shaft of the Happy Jack has been re-timbered and is being sunk 200 ft. The vein shows a width of 14 to 16 ft., assaying 36 oz. silver and \$3.20 gold. The driving of the Maynaugh adit is making rapid progress. The adit on the Link group is in 105 ft. and cross-cutting is progressing. The Shepherd is developing well, with a large tonnage of ore assured.

The drift from the 900-ft. level of the Rochester mine broke into milling ore last week and is expected to intersect the rich vein exposed on the 800-ft. level at any time. The drift from the 700-ft. level is also nearing this vein. Both drifts on the 800-ft. level are still in ore of shipping grade. A large output is maintained from the 100, 420, and 650-ft. levels, and the mill is running at capacity.

Rochester, June 2.

MINERAL COUNTY

(Special Correspondence.)—With more than a score of properties producing, the Luning district is established among the leading copper districts of the State. Many companies are now strongly financed, and several reduction plants are contemplated. The Pilot Copper Co., of New York, has arranged for the construction of a leaching-plant, which will treat custom ore besides the company product. The Calavada, Empre-Nevada, Nevada Champion, Luning-Idaho, and many others are developing well.

Equipment has been ordered for the new main shaft of the Luning-Idaho, which will be sunk 500 ft. Machinery includes a 50-hp. hoist, compressor, and drills. A small hoist is to be placed at the McDavitt shaft. The Hahn adit is in 535 ft. and has cut two shoots of copper-gold ore. In the Erickson adit ore assaying \$36 per ton, principally in copper, has been exposed. In the old workings a large tonnage of shipping-ore is exposed and preparations have been made for shipments. R. H. Todd is superintendent, and John C. Skuse is consulting engineer.

Near Rand the Jumbo Extension company is developing the Copper Mountain mine. A powerful hoist and compressor have been installed on No. 2 shaft and equipment erected on shaft No. 1. In both shafts good ore is showing, and drifts from No. 2 have intersected the orebody developed in the Miller-La Patt lease. Outlying territory is being explored with a core-drill. A spur-track to the mine is being extended from Nolan, the nearest railroad station.

The Queen Regent Merger company expects to have the new hoist and compressor in operation in a few days, when sinking of the 500-ft. shaft another 100 ft. will be commenced. Early shipments are planned from the 500-ft. level. On the 300 and 400-ft. levels the vein is from 10 to 30 ft. wide, with the ore assaying \$10 to \$20 per ton.

The Nevada Rand company has completed sinking of the shaft to a depth of 450 ft. and is cross-cutting from this point. The vein has been cut and drifts are being extended in search pay-ore. Near the 180-ft. level excellent ore is showing.

Luning, June 5.

NYE COUNTY

(Special Correspondence.)—An extremely heavy flow of water was encountered in the shaft-sinking at the White Caps a few days ago. It was necessary to devote practically the entire week to the work of fighting the water.

The regular sinking-pump, a No. 5 Cameron air-pump, for a time was unable to keep the water down. An additional sinker, a No. 7 Cameron, was brought from Tonopah and is working in conjunction in the shaft-draining operations. Since the second pump has been working, the flow has diminished and the miners are at work in the shaft bottom, and from now on little trouble with the water in the shaft is expected. The shaft is now 72 ft. below the fourth level. In the east drift, the water is decreasing, though no further development has been done since the water was struck two weeks ago. Several drill-holes have been put in the face of the drift to expedite the draining of the water. To handle the water from the levels, the large station-pump on the fourth level, a 6 by 8-in. triplex, now has an 18-in. pulley replacing one of 12 in., thus speeding up the pump. The 4 by 6-in. triplex on the third level also is kept working. The total volume of water from the four pumps is 375,000 gal. per day. The mill is nearly finished. The brick-work of the first hearth and the centre-column of the Wedge roaster is nearing completion. The elevator-hoist for the roasted ore has been raised into position, ready for operation. In the tank-building, the canvas and cocoa-matting bottoms for the leaching-tanks have been laid, the piping to the fresh-water storage-tanks above the mill is complete, and within the next few days all the mill tanks will be filled with water. The machinery in the roll-house is being installed; the trommel is in place, also the whip-tap shaking-screen. The Pipe Springs cut-off wagon-road has been completed to the bottom of the hill east of the first summit from the mine. The road should be ready for use within two weeks. The plans for the White Caps assay-office have been drawn and work will be commenced on the building as soon as the rush of mill work has slackened.

At the Manhattan Consolidated Mines Development Co.'s property the lateral work from the shaft on the 300-ft. level has reached a point 110 ft. east. The drift has been running parallel with the mud-dike, the strike of which is 70° north of east. The direction of the drift was changed, the last 10 ft. being run 25° south of east, which will bring the line directly across the mud-dike, and should reach the vein at a point nearest to the shaft. The last 10 ft. of the drift has shown more water than previously. The water in the mine so far has been handled by bailing, but at any time the pumps may be required.

At the Morning Glory the shaft has reached a depth of 100 ft. where there is a change in the formation, the limestone being silicified, and showing considerable iron, although some sulphide also shows. The management announces that a 50-hp. three-drill compressor has been purchased from Silver Peak. The new 45-hp. electric hoist is being installed. It is planned to erect a large engine-house so that both the hoist and compressor can be placed under one roof.

The east cross-cut in the Extension mine from about the 100-ft. level has been following a break in the lime, and has been in medium-grade ore for 10 ft. Some sulphides show in the floor of the cross-cut near the face. This apparently is the same formation as that seen in a large cropping on the surface. Upon reaching greater depth a large orebody is expected, judging from the conditions as developed.

The east drift from the 600-ft. level in the Amalgamated has been extended 42 ft. during the week, now being out from the shaft 252 ft. Ore from development work in the vein, No. 2 raise and from stope No. 4 west, has supplied the mill during the week. The fissure and No. 4 stope, west, carry the usual grade of ore. No. 2 west, on the hanging-wall vein has shown improvement in the last 10 ft. Indications point to the foot-wall vein making ore in this territory.

The shaft in the Red Top is down 90 ft. and is in heavy blue lime, having passed through the broken limestone which carried some gold. The footage made in sinking has been all by hand work, and most of the time in very hard ground.

The three sets of lessees operating on the southern part of Union No. 9 claim of the Dexter Company are extracting ore. In each case cross-veins have been discovered and high-grade ore is being hoisted. The Juhl-Fogle lease has reached a depth of 100 ft. and they are stoping very rich ore.

The drift west from the Doris working-shaft is in a porphyry dike, and the face shows considerable oxidized ore, carrying gold. The porphyry is more silicified as the drift advances, and it is expected soon to reach a vein.

The raise from the 300 to the 200-ft. level north from the working-shaft in the Big Pine, under the north glory-hole, holed-through yesterday. The Big Pine has been one of the most important and regular producers in the district. The north glory-hole produced ore which averaged in the mill \$3 in gold. The Big Pine mill has neither rolls nor stamps. From the Gates rock-crusher, the ore goes to the tube-mill, one of the largest in use in Nevada, and from there over the plates; the oversize from the tube-mill, through a closed-circuit returning for re-grinding. In one part of the mill iron balls are used and in the balance of the mill Maris chalcedoney pebbles, a local product, are employed for the fine-grinding.

The winze to the west of the shaft in the Train Chase lease on the Mustang, has demonstrated that the last 30 ft. carries rich sulphide gold ore. In the east winze the character of the high-grade ore is changing into sulphides. As fast as the ore is mined it is sacked and hoisted to the surface, for shipment to the smelter. Two shifts are engaged on the lease. It is stated that the new management intend to commence mining operations in the old company working-shaft.

At a special meeting of stockholders of the Mustang Extension Mining Co., the articles of incorporation were amended to increase the capital stock of the company from 1,000,000 to 1,500,000 shares. It is planned to place the additional stock in the company treasury to obtain funds for carrying forward an extensive campaign of development.

Manhattan, June 7.

OREGON

JACKSON COUNTY

(Special Correspondence.)—Several Gold Hill miners returning from the Buzzard mine in the Elk Creek district, 40 miles north-east of Gold Hill, report that the lessee, Paul Wright, is making good progress in the development work at the mine. The new work consists of an 850-ft. drift on a stringer of sulphide ore on the opposite side of the hill from the old works. This drift will cut the main vein at a depth of 300 ft. The work is being crowded with two shifts. The old works consists of 3009 ft. of drift. The greatest depth is 170 ft. on the vein. The orebody strikes north-west.

The property is owned locally by the Pearl Mining Co., of Central Point. The machinery equipment consists of a jaw-crusher, a small Huntington mill, and a Frue-vanner, operated by steam-power.

Some of the highest grade sphalerite known in the State has been produced from this mine. The last shipment made late in 1916, consisted of four tons, which returned \$2100.

Elk creek is a new district in the north-eastern part of the county; Gold Hill being the nearest and most practicable shipping-point. The geology of the district consists of a series of flat-lying Cascade andesite flows. Vertical fissuring has taken place locally, producing fractured zones, which furnished opportunity for the mineralizing waters to deposit ore in the crushed or brecciated rock. It is a heavily forested area and is within the Crater National Forest. The elevation of the district varies from 2000 to over 5000 feet.

Gold Hill, June 6.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

DAVID J. PULLINGER is at New York.

JAMES M. HYDE is at Ouray, Colorado.

WALTER DOUGLAS is at the Fairmont hotel.

CHARLES BUTTERS has gone to Washington.

WILLIAM W. MEIN is expected here shortly.

ALF WELHAVEN sailed from Korea on June 6.

BERNARD MACDONALD is leaving for Antofagasta, Chile.

F. A. BEAUCHAMP will be in Arizona for several weeks.

W. L. WATTS has returned to Los Angeles from Vancouver, B. C.

C. E. WUENSCH, on his return from Salvador, has gone to Arizona.

HERBERT C. CHARLES, recently at Lovelock, Nevada, is in San Francisco.

JOHN H. EGGERS is making a trip to Arizona to make an examination.

J. S. DILLER was in San Francisco and has gone to Porterville, California.

J. E. SPURR passed through San Francisco on his way to British Columbia.

CURTIS H. LINDLEY has gone to Washington to co-operate with H. C. HOOVER.

R. S. BLACK has been elected president of the Australasian Institute of Mining Engineers.

L. D. MILLS, of the Merrill Metallurgical Co., has been at the Portland mill, Cripple Creek.

G. W. LAURIE is superintending the building of a copper-concentrating plant at Baltimore, Maryland.

H. G. YOUNG has been granted a commission in the Canadian Engineers, and is now at St. Johns, Quebec.

W. E. FENWICK has resigned the superintendency of the Francisco mine at Acostas, Pinar del Rio, Cuba.

W. R. DEGENHART sails for Burma on the 16th inst., returning to Bawdwin mines of the Burma Corporation.

C. C. EVERENHAM, of the Dome Mines, Porcupine, has been visiting the Portland mine at Cripple Creek, Colorado.

E. GYBON SPILSBURY sailed from New York on June 5 for Central America and expects to be absent until the middle of July.

H. DES. KENNEDY is in charge of the construction of a 200-ton mill for the Boston American Mining Co., at Monte Cristo, Washington.

JAY LONERGAN has retired from the professorship of mining engineering in the University of Peking and has returned to the United States.

JOHN A. FULTON is acting manager for the Melones Mining Co., California, in the absence of W. G. DEVEREUX, who is engaged in military duty.

ROBERT S. LEWIS has returned to Salt Lake City, after examining a mine in Arizona. He will spend the summer at Huntington Lake, California.

JULIUS M. COHEN, manager for the Croesus Gold Mines, Limited, at Matheson, Ontario, has been appointed a first lieutenant in the United States Reserve Corps.

O. H. REINHOLT has returned to San Diego from Inyo county, and is now on his way to examine properties in the Middle West, and as far east as Birmingham, Alabama.

SAMUEL W. COHEN, general manager for the Crown Reserve Mining Co., Ltd., and the Porcupine-Crown Mines, Limited, has returned to Montreal after a two months trip to California.

W. J. PIKE, for five years superintendent of the Jim Butler mine at Tonopah, has resigned and is now superintendent for the Consolidated Spanish Belt Silver Mining Co., also at Tonopah.

THE METAL MARKET

METAL PRICES

San Francisco, June 12

Antimony, cents per pound	21.50—22.00
Electrolytic copper, cents per pound	34.50
Pig lead, cents per pound	12.25—12.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$90
Spelter, cents per pound	11.50
Tin, cents per pound	60
Zinc dust, cents per pound	20

ORE PRICES

San Francisco, June 12

Antimony, 50% metal, per unit	\$1.55
Chrome, 40% and over, f.o.b. cars California, cents per unit	50—55
Magnetite, crude, per ton	\$8.00—12.00
Tin, cents per pound	60
Tungsten, 60% WO ₃ , per unit	20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 45% (under 35% metal not desired), cents, unit	36—38

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese	Per unit \$1.00
46 to 49% metallic manganese	0.98
43 to 46% metallic manganese	0.95
40 to 43% metallic manganese	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

EASTERN METAL MARKET

(By wire from New York)

June 12.—Copper is firm, with futures stronger. The price has been 32.75c. throughout the week. Lead is strong and higher at 11.75 to 12c. Zinc is dull but firm at 9.75c. all the week. Platinum remains unchanged at \$105 for soft and \$111 for hard.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver

Date	6	7	8	9	10 Sunday	11	12	Average week ending
June	75.25	75.12	75.05	75.02	76.37	77.00		74.06
May								74.02
Jan.	1915	1916	1917					74.06
Jan.	48.85	56.78	75.14					74.02
Feb.	48.45	56.74	77.54					74.09
Mch.	50.61	57.89	74.13					74.78
Apr.	50.25	64.37	72.51					74.82
May	49.87	74.27	74.61					75.83
June	49.03	65.04						

The weekly letter of Samuel Montagu & Co., of London, on May 10, says:

During the week the market has been exceedingly quiet, and there being but little competition for the small amounts offering, the price has shown a drooping tendency. There was sufficient inquiry on Friday, May 4, to maintain the price at 38½d., but on Saturday it fell ¼d. A further fall of 1/16d. occurred on the 7th, bringing the quotation to 37 15/16d., at which figure it remained until the 9th, only to drop a further 1/16d. today, when it was quoted at 37½d.

The sales from New York continue very small and there is but little speculation either in buying or selling.

The following is taken from the 'Times' of May 4: "According to the Schleswische 'Grenzpost,' nickel and silver coins will shortly be cancelled in Germany and replaced by others of metal or by paper. This is due to the increased hoarding that is going on."

As far as silver is concerned this threat is not very terrifying, inasmuch as those who are now hoarding silver marks are doing so because they believe that after the War these coins will very likely be more valuable as bullion than as currency.

The stock in Bombay consists of 1700 bars as compared with 1500 bars last week. The stock in Shanghai on April 5 consisted of about 27,500,000 oz. in sycee, and \$17,600,000, as compared with about 26,800,000 oz. in sycee, and \$17,400,000 on April 28.

TIN

Prices in New York, in cents per pound.

Date	6	7	8	9	10 Sunday	11	12	Average week ending
Jan.	34.40	41.76	44.10					37.38
Feb.	37.23	42.60	51.47					34.37
Mch.	48.76	50.60	54.27					33.12
Apr.	48.25	51.49	55.63					33.00
May	39.28	49.10	63.21					39.50
June	40.26	42.07						38.71

Tin has been the principal item of Bolivian export for many years, the bulk of the production having been shipped to Great Britain, even after

the War broke out. During 1915 about 35,360 metric tons of 2204.6 lb. of tin ore was sold to Great Britain, while the United States, which held second place on the list of buyers, received only about 1100 tons. During 1916, however, the United States purchased this mineral in increasing quantities, and it is estimated that about one-half of Bolivia's production is now being sent to the United States. The total exportation of this ore during 1915 was about 36,492 tons. In addition to the exports to Great Britain and the United States, Germany took 27 tons, Argentina, 2 tons, and Uruguay and Chile, 1½ tons.

COPPER

Prices of electrolytic in New York, in cents per pound.

May	75.00	80.00	104.00					101.50
June	90.00	74.70						123.00

ANTIMONY

The metal is lower on less demand and large arrivals. Chinese and Japanese grades can now be obtained for early delivery at 21 to 22c., duty paid, New York.

PLATINUM

Platinum is quoted at \$105 for soft unalloyed metal and \$111 for the hard natural platinum-iridium alloy.

ORES

Tungsten: Some dealers report that considerable business has been done in the past 10 days both for domestic and foreign account, while others say that little demand has appeared, indicating that it depends on the dealer as to just what view of the market is obtained. Unquestionably sales have been made for both accounts, and in some quarters the statement is made that not enough ore, especially American, is available. The quotation is firm at \$20 per unit for 60% concentrate. Ferro-tungsten is quoted at \$2.25 to \$2.50 per lb. of contained tungstic acid, some stating that it might be shaded down to \$2 to \$2.15.

Molybdenum: The market is firm at \$2.20 per lb. for molybdenum in 90% ore. Some business has been done at this figure.

Antimony: Contracts for ore from South America are reported closed at \$2.35 to \$2.40 per unit.

Eastern Metal Market

New York, June 6.

The metals are all quiet and dull though mostly strong. The holidays, one on Decoration Day and another on registration day yesterday, which was almost entirely a holiday, have tended to lessen business.

Copper is quiet, but has a firm undertone with an advancing tendency.

Zinc is dull but steady and firm.

Lead continues to maintain and, if anything, to increase its strength.

Tin is lower and less active.

Antimony is again lower but very quiet.

Transactions in the pig-iron market the past week confirm what has been well-considered opinion in the steel trade for some weeks, that future war advances were likely to come as abruptly as any that have come in the past two years and might go to lengths even now thought impossible. The arrival of \$50 pig iron was seen at Pittsburg last week when Bessemer iron, to the extent of 75,000 tons, was sold at from \$46 to \$50 per ton, 20,000 tons having gone at the latter price. Semi-finished and finished steel have been affected by these sales and have advanced too. All steel-scrap markets have also been stirred and heavy sales at advancing prices are recorded. The labor-supply is causing concern. At Chicago the exodus of men to farms is a serious factor and steel-mills and machine-shops generally will need Government help in order to maintain forces in the face of the new conscription movement.

Pig-iron production in May was 3,417,340 tons, or 110,238 tons per day against 111,165 tons per day in April. But the number of furnaces now on the active list was 340 on June 1, the largest number in many years.

COPPER

Copper prices for nearby delivery, such as June and July, are largely nominal at 32.50c., New York, for both Lake and electrolytic, with metal for these deliveries obtainable generally only through second hands. Quotations for spot delivery are quite a little higher, but vary according to seller and conditions from 33 to 34c., New York. The situation as to third quarter, or really only August and September, is mixed, quotations varying from 30 to 32c., New York, with fourth quarter pegged at 29 to 30c. In general there has been nothing going on in the past week, due to holidays and general lack of demand. The market is quiet but very firm, with the tendency upward. Business of any volume for any position is not reported, though a little has been done here and there as always. No news is forthcoming regarding the probable needs of the Government and its allies nor as to the price to be paid. Some think there will be a scarcity when full demands are realized in spite of the fact that production is very large. The question as to the price to be paid by the belligerents continues to be discussed with the preponderance of opinion in favor of not less than 24 to 26c. per lb. But there are some who favor openly a much lower price and openly publish their views and arguments. As bearing on this point the following comment by a prominent critic is of interest:

"Something was said in Congress last week about 'the men who are holding the price of copper up to 30c.' The price is being maintained by a thoroughly legitimate excess of demand and not by manipulation or speculation. The Congressmen who make the attack on the producers probably would be surprised to know that it would be impossible for him to buy 1,000,000 lb. of copper from any of the large producers in the United States if he were to appear in person with cash in hand. The producers make it a rule not to sell copper to speculators, insisting in all cases that the purchaser must be a *bona fide* consumer or the representative of one.

"There is no copper trust, no regulation of prices, and the producing companies are exerting every power they possess to increase the volume of their output. There is no more reason why copper should be sold at cost, at the average price of the past ten years, or at any other price than that established by demand and supply, than there is that metals in general, including gold and silver, should be so sold. The Government's recent purchases of silver at much higher prices than the average of the past ten years provoked no discussion in Congress. There is now every indication that consumptive requirements, including those of the great War, will continue to exceed production. Unless the volume of output can be increased further, or consumption in industrial lines decreased, the metal is likely to sell considerably higher."

TIN

The tin market is always affected by holidays, perhaps more than other markets. With Decoration Day last week and practically a holiday on registration day yesterday, together with an intervening Saturday, the market has been decidedly quiet—in strong contrast to the past two or three weeks. It has come almost to a halt, due largely to conditions at Washington. On a small volume of business prices have declined considerably the past week or from 65c. on May 28 to 60.25c. yesterday, a decline of nearly 5c. per lb. in a week. This has been due to several causes. Lack of demand is one, and larger arrivals another, but the feeling is growing stronger that shipping permits from England will be easier if anything. It is expected that the monthly statistics, not yet available, will show a considerable increase in the visible supply. It is also interesting to note that the Straits shipments of tin for May totaled 6866 tons against 3965 tons in May, 1916. Of decided influence, as affecting the decline here, has been the fall in prices in the London market. Spot Straits was quoted there yesterday at £239 15s., which is about £14 per ton less than it was a week ago. Arrivals to June 4, inclusive, are reported as 300 tons, with the quantity afloat, 2052 tons. The average price for tin for May was 63.21c., New York.

LEAD

Lead has been the only interesting market of the week. It has been and is still very strong and advancing, but the tendency has been ragged. Large producers continue more or less out of the market and hence supplies are not abundant. Re-sale lots have appeared, but the interesting feature is that both the St. Louis and New York prices are on a level at 11.50c., which is rather unusual. Some business has been done at less than this, at 11.25c., New York, but it has been only in odd lots. The Government's needs are still a mystery, but it is known that they will be large, and a strong market is confidently expected for some time to come. The quotation of the American Smelting & Refining Co. is unchanged at 10c., New York, though it was expected that this would be advanced on Monday. The spread between this price and that of the open market is 1½c., or the largest ever known. An advance to 10.50c., or even 11c., is not improbable in the near future.

ZINC

The market continues firm and dull. Demand is not active, but underlying conditions are such as to make it strong. One dealer terms it a 'curious market' in that it is not only dull and inactive but futures are really higher than early deliveries. The former has been sold as high as 9.50c., St. Louis, or 9.75c., New York, while metal for early delivery can be obtained for from ½ to ¾c. lower. The general expectation is that in the not distant future higher prices will probably prevail, and sellers are reluctant to part with their metal except at satisfactory prices. Demand is not strong for any position.

EDITORIAL

T. A. RICKARD, Editor

CAN any of our readers give us information concerning the use of soluble frothing-agents prior to April 1909? The matter is one of great interest, in view of the Minerals Separation claim to a monopoly in the use of such agents in flotation.

ELECTROLYTIC ZINC will soon be produced from a plant having a daily capacity of 10 tons that is now being erected by the Bunker Hill & Sullivan company at Kellogg, Idaho. This is but the first unit of a large reduction works that later will treat zinc concentrate obtained as a by-product from many of the lead mines of Idaho.

PIG-IRON is selling at \$50 per ton, and Connellsville coke has merrily followed its crescendo with large sales at \$9.50. Predictions of \$75 iron are freely made in view of the singular phenomenon that 'futures' in the iron-market are quoted at a higher price than the 'prompt' metal. These exaggerated quotations are due to active bidding among buyers for a place as preferred customers to meet their needs under contract for later delivery of manufactured articles.

STOCKS of metal held by the American Smelting & Refining Company are said to be carried on that company's books at 12 cents per pound for copper, 3.88 cents for lead, and 5.50 cents for zinc. Comment on these figures has been made, the company being praised for its conservatism. The figures are interesting, because, of course, they represent an estimate of cost, it being customary among manufacturers to inventory their product when in stock at cost. Moreover, the estimate of cost, in each case, seems to us in accord with facts.

COPPER is the subject of an interview with Mr. Adolph Lewisohn in the *Magazine of Wall Street*. Mr. Lewisohn's opinions on the subject command respect. He says that a large demand for copper will persist for the duration of the War; spot metal is scarce and there is a constant call for late delivery, owing, in part, to the requirements of the shipping industry. As to the market after the War, he expects Germany to become a large purchaser, but he suggests that the Germans may have found a substitute for copper in the manufacture of munitions and they use a good deal of this copper over and over again. He is of the opinion that copper shares are "cheap" now, but this seems an optimistic touch, having regard to the probable regulation of price by the Government, acting not only for the United States, but for our Allies also. Mr. Lewisohn

hazards the guess of an average price of 20 cents for the next decade and suggests extremes of 15 and 25 cents per pound. This seems to us reasonable.

ONE of the most important mineral discoveries made on the Pacific Coast during recent years is that of several large masses of high-grade magnesite in the State of Washington, between the towns of Chewelah and Valley, 32 to 35 miles north of Spokane on the Great Northern railroad. The various deposits are from 8 to 13 miles from the railroad. They consist of interbedded masses, 200 to 400 feet wide, of coarsely crystalline magnesite lying between quartzite and mica-schist. The magnesite is incased by a selvage of brucite, a magnesian hydroxide related to serpentine. An estimate of as much as 4,000,000 tons in one of the quarries, the Finch, has been made. The croppings extend for several miles. We understand that the whole group of properties has been acquired by Mr. D. C. Jackling.

SOME weeks ago we called attention to the wise provision by which cyanide from the works of the Cassel Cyanide Company of Glasgow was being supplied to the Canadian mines at 15 cents per pound. This, of course, was a war measure, under control of the British government, and was meant to insure continuance within the Empire of the precious metal production dependent upon this solvent. The question of cyanide manufacture is reviewed at some length in our Discussion department this week by Mr. James A. McRae. It is suggestive comment, and should lead to consideration of definite ways and means for assisting precious-metal mill-men in this country. Cyanide is necessary in facilitating the output of the metals needed in exchange, and fundamental to finance. It would seem pertinent to our own needs that cyanide production should also be regulated in America.

DETAILS of a simple, effective self-dumping arrangement for use in connection with skips, are given by Mr. H. Vincent Wallace in an article appearing in this issue. It is the kind of practical wrinkle that appeals to men in charge of mining. In addition to the safety and economy of the device, it is worth while to call attention, not only to the ease with which it can be manufactured in the shop at the mine, but to the tribute paid by Mr. Wallace to the skill of the Mexican blacksmith who made the one in use at the Nueva Luz property, and also to the efficiency of the workmen operating the appliance. This is in line with comment by other engineers, recently published in this paper, emphasizing the economic wisdom of utilizing native talent for practical mechanical operations conducted in foreign countries. To take ad-

vantage of such ability requires the right sort of spirit in the manager. Some persons never discover the latent talents in men of another race. To get a response in which he reveals the capabilities that lie within him, the manager must also be able to respond to the psychologic peculiarities of the employee, and this can never happen when the engineer in charge cherishes a disposition to depreciate his workmen for racial reasons or any other.

GOVERNMENT statistics show that the smelter production of primary copper in the United States during 1916 was 1,928,000,000 pounds, as compared with 1,388,000,000 in 1915, this being an increase of 39%—a huge gain. The difference in value is even bigger, the two totals being \$474,288,000 and \$242,900,000. Arizona was easily first with an output of 694,847,307 pounds and Montana second with 352,139,768 pounds. The apparent consumption of copper in this country during 1916 was 1,429,755,266 pounds, as against 1,043,461,982 the year before, this being an increase of 37%. If to the new refined copper is added the secondary copper and that in alloys produced during the year, it will be found that a total of over 2,000,000,000 pounds of copper was available for consumption.

WE note with pleasure that an American Committee of Mining Engineers in London has been organized "for assistance in the prosecution of the War." Among those instrumental in forming this committee were Colonel J. W. Boyle, Colonel Millard Hunsiker, W. B. Poland, R. Gilman Brown, D. P. Mitchell, Millard Shaler, Norman C. Stines, and Chester W. Purington, the last mentioned being honorary secretary. The purpose is to make such suggestions to the Government of the United States as may be useful in carrying on the War and "to offer the services of the committee for consultation and advice to representatives of the American government should this be desired." The idea has been received most courteously by the Ambassador, Mr. Walter Hines Page, in London. A sub-committee has arranged to go to Petrograd with the object of assisting in the organization of Russian railway transport.

Our Purpose

The statesmanlike opportunism of the President has been shown in many ways during the great crisis, notably by the speech made on Flag day, June 14. In paying an eloquent tribute to Old Glory he took the opportunity of informing our people why we have gone to war. His explanation will be convincing, not because Mr. Wilson is a student, or a professor of history, but because he is the President who was re-elected last November for the reason that "He kept us out of the War"—as long as he could—as long as the honor and safety of the United States permitted. His sincerity of intention is accepted and for that reason, among others, he is receiving generous support. The success of the Liberty Loan proves it; so does the general awakening of the popular intelligence to the realization of our concern in the calamitous

events that have ensanguined the face of Europe, and some other continents also. Even now we are not fully awake to the intensity of their meaning, simply because physical distance obscures; for even the peoples of Europe, the British particularly, were slow to realize the bloody reality until it had been brought home to them by Zeppelin raids and by the wounded returning from the fighting on land and sea. We are facing the most stupendous crisis in all human history. "If the military masters of Germany succeed, they will be safe, but Germany and the world will be undone," as the president said; "if they fail, Germany is saved and the world will be at peace. If they succeed, America will fall with the menace." The German military machine was organized to make this earth impossible for any but the cogs in that relentless juggernaut of devastation. The world cannot remain "half slave and half free." Either the non-moral conscienceless domination of a military caste is to prevail and democracy be sent—where civilization is already—to the shambles, or the wrong-headed hysteria of a great people must be cured by defeat, and representative government emerge triumphant from the welter of war. "The world must be made safe for democracy or it will be rendered secure for military autocracy." A few months ago there were many who said "It is none of our quarrel; let us keep out of it." That seems long ago. A succession of maritime assassinations provoked our resentment, the enslavement of civilians in unhappy Belgium stirred our sympathy, the Zimmermann note shocked us into recognition of the sinister forces at work, not only to conquer Europe, but to threaten this continent. Then we realized that this was no European war. It is a world-war, a contest for the liberty of the nations on every continent, and more particularly for that freedom to live and let live which is the heritage bequeathed alike by the men that fought under Washington and by those that fought under Lincoln. The American idea is at stake, "the right of those who submit to authority to have a voice in their own government," we fight that "representative government shall not perish from the earth"; we fight also for "the liberties of the small nations, for a universal dominion of right by such a concert of free peoples as shall bring peace and safety to all nations and make the world itself at last free."

Truly we have a great cause. For more than two years we stood safely outside the great calamity; we prospered by the necessities of the fighting nations on the other side of the Atlantic; we took their gold until we were gorged with it; they jibed at our apparent gluttony; they sneered at our seeming timidity, but they are answered now. No nation ever risked its blood and its treasure so disinterestedly as the United States has done in coming to the aid of the Allies—now our Allies. Endangered we may be by German designs of overseas conquest, but not many of our people thought so when they put their hand into the President's and vowed to see this thing through. Our task is greater than self-interest and more glorious than self-defence. For human freedom and political liberty we risk everything; "To

such a task we can dedicate our lives and our fortunes, everything that we are and everything that we have."

The Miami Appeal

In our issue of June 2 we gave a telegraphic summary of the opinion of the United States Circuit Court of Appeals for the Third Circuit, at Philadelphia, in the case of *Minerals Separation* against the Miami Copper Company. This case had been appealed from the District Court of Delaware, at Wilmington, as our readers will recall. We published the text of the decision of the lower court in our issue of October 14, 1916. In our last issue we gave the majority opinion of the appellate court in full, and in this issue we reproduce the text of the minority opinion. The result, on the face of it, is favorable to the patent monopoly claimed by Minerals Separation, but, like the earlier decisions, it leaves large openings both for evasion and misunderstanding, and, like its predecessors, this latest judicial pronouncement presents points of disagreement with the various courts that have previously spoken. It will be noted that the majority opinion of two judges is vigorously opposed by the minority opinion of one judge. That Judge Woolley, who recorded the majority opinion, should not agree with Judge Buffington, who gave the dissenting opinion, will not surprise those that have read the record in the case, for the colloquies of these two judges with the various counsel disclosed, it seemed to us at the time, the trend of their thinking. The opinions are long, as if the judges desired to explain and defend their views. We shall not complain of that, because it is interesting to follow their ratiocinations. Judge Woolley goes into the technology of the subject and makes several obvious slips, which need not detain us. He, in voicing the majority opinion, interprets the Supreme Court decision in the *Hyde* case as meaning that "invention resides not alone in the critical proportion of oil, but also in air and agitation," or, as he expresses himself elsewhere, "in the co-action of the critical proportion of oil and air effected by 'an agitation greater than and different from that which had been resorted to before,' resulting in a froth concentrate of economical value." The learned judge must have meant 'economic.' The question therefore was whether the Miami practice was within the scope of the patent thus interpreted. The Supreme Court had established the validity of the patent, No. 835,120, but it "did not construe the patent or determine its scope." Minerals Separation claimed that the Miami operations were within the scope of their patent; the Miami company denied it. The Court of Appeals asserts that "the positions of both parties are extreme," and then makes the important criticism that "the contention of the plaintiff at least omits the very definite limitation of the patent to the results obtained by the use of oil with the described proportions [which, as our readers are aware, have been demonstrated, since then, to be non-essential and based upon a misunderstanding of the technology of the process], and also the equally definite disclosure of an agita-

tion in violence and duration greater than before employed, while the defendant misinterprets words of description as words of limitation." This last refers particularly to the use, by the Supreme Court, of the phrase "by beating the air into the mass," when describing the agitation precedent to froth-flotation. Judge Woolley holds that the words quoted by the Supreme Court were not taken from the patent, but from the testimony of a witness for the patentees, and he proceeds forthwith to state his conclusion that the Supreme Court did not limit the agitation of the patent "to agitation by mechanical means," but to agitation of a violent and persistent kind. The agitation does several things, some old, some new. "It mixes the oil with the metal of the ore. This is old. Then, *by its greater intensity and longer duration*, it stirs the pulp into a froth." Here is the crux of the case; the agitation that is greater in intensity and longer in duration than anything heretofore used is the novel agitation of the patent in suit, by reason of which the Supreme Court upheld the patent. It is significant, and important to the art, that this decision of the Third Circuit Court of Appeals holds that the mixing of the oil with the mineral in the ore is old, because it leaves open the use of oil in connection with aeration-cells. The question therefore is whether the agitation produced in the Miami mill was of the prescribed violence and persistence. The defendant said that it was nothing of the kind, merely a gentle rising of air through the pulp "without any agitation whatever," claiming that "nowhere in the process is there agitation, or that, at most, there is only such agitation as appears in the prior art." As the Court says: "The controversy revolves around the elements of aeration and agitation." The Court then proceeds to consider (1) the use of the centrifugal pump, (2) the use of the Pachuca tank, and (3) the use of a break in the circuit. All of these three methods the Court holds to be the agitation in degree of intensity and time of duration of the patent, as defined by the Supreme Court. The Miami company was unfortunate in using the devices mentioned, for it is known now, and it was known before the case was first tried, that none of them was essential. Judge Woolley refers to the fourth method, in use at Miami, in which the Pachuca was not used, nor the centrifugal pump, only a bucket-elevator, but he ignores the fact, to which his attention had been drawn during the argument by defendant's counsel, because as he says, "we cannot consider and adjudge with propriety or authority a process with respect to which the plaintiff has had no opportunity to produce testimony and which was not embraced in the decree we are reviewing." Since the case was first tried the machines that appeared to the Court to necessitate violent agitation of the pulp have all been discarded, so that the decision is already out of date, just as the Supreme Court's dictum concerning the 'critical' proportion of oil was stultified, by technical practice in several mills, within a month after it had been promulgated. Having its eye on the centrifugal pump and the Pachuca tank (more properly called the

Brown agitator), the Court says: "When the critical [now mythical] quantity of oil is used and fomentation [or Fromentation] is produced by agitation, which in degree of violence and in duration is substantially that of the patent, clearly it is indifferent whether it is attained by mechanical or other means, for the patent deals with agitation as a means of developing the discovery, not with means for developing agitation." Hence the verdict on the issue of infringement; but the decision goes farther: it validates the use of the pneumatic cell in flotation. The Court says concerning the Callow cell: "Aeration is direct and is not the result of or caused by agitation. On the contrary, agitation results from aeration, and such agitation, though present in some measure, is not even approximately of the violence and duration of the agitation of the patent. The operations of the Callow cell certainly possess these distinguishing features from operations of the process where aeration is caused by agitation." On the next page of the opinion the Court confirms this important dictum by saying: "If the only agitation to which the pulp was subjected (after such agitation as in the prior art was necessary to mix the oil and ore) was the agitation of the Callow cells, we would not say that that agitation amounted to or was the equivalent of the violent agitation of the patent disclosure and constituted infringement." Apparently, if the Pachuca and pump had not been in evidence, the Court would have given a different decision. As it now stands, the Philadelphia decision clears the ground in that it leaves free the use of the Callow cell, in conjunction with such agitation as was used in the prior art solely for the purpose of bringing the oil in contact with the mineral; in other words, unless the use of the flotation process involves the use of an agitation characterized by great intensity and long persistence, as set forth in patent 835,120, it will not be held to infringe.

This interpretation of the majority opinion is sustained by the minority opinion, in which Judge Buffington states plainly that the case involves the question "whether any and all advance and improvement in the sphere of air flotation in mineral recovery for the next few years shall be subjected to what will practically be a blanket claim for any use of air as a flotation agency." He places himself on record squarely against anything of the kind, explaining why patent 835,120 should not be given the right to "paralyze the subsequent development of a great art." The patent, he says, does not give Minerals Separation the right "to monopolize all air flotation with a limited use of oil, but an unlimited use of agitation." The claim cannot be broader than the invention. That invention was based upon the quantity of oil, the character of agitation, and the resultant froth, but it is clear that the discovery, if it be such, is botomed on a new kind of agitation that made possible a new extension of well-known properties of oil in a direction not reached by any previous methods of agitation. "The specification does not purport to disclose or to make use of any newly discovered property of oil. Let

that be clearly understood," says Judge Buffington. "The oil required and used for covering or coating the mineral particles was precisely the same in quantity and function in prior practice and the practice of this patent. But what did happen was that the violence and duration of the agitation brought more particles into contact with oil than when the agitation was less violent." Elsewhere he says, "as the amount of oil was decreased, the amount of agitation had to be increased." What, then, was the disclosure? The Judge answers his own question by saying that it was the use of the Gabbett type of mixer, obtaining thereby the type of agitation essential to the process of the patent in suit. Thus it will be seen that the two opposing opinions of the Court are not so divergent as their verdicts would lead one to expect. If only the Miami management had not used the centrifugal pump and the Pachuca agitator in its early operations! But Judge Buffington says that, as the pump was discarded before the trial, no logical grounds existed for the patentees "planting themselves on the position that the pulp-lift of a centrifugal pump is air-agitation of their disclosure and claim." This minority opinion furnishes a powerful argument against Minerals Separation. Judge Buffington quotes the testimony of the three patentees to show how they laid stress on the "intentional beating in of air," and concludes that the basis of the invention was "agitation of a particular type and power," the use of which "led to the further discovery that all oil except the minimum required for mineral coating could now be dispensed with." Thus the so-called critical proportion of oil does not suffice to produce the process in suit; the Judge makes that evident: "That the invention cannot be based on the use of a minimum of oil alone is clear, for the stress laid on agitation in the specification and its presence as an element in the claim here in issue forbid any such holding, and the further fact that a claim based wholly on the use of a fraction of 1% of oil for coating minerals was abandoned during the prosecution of the patent." He points to the fact that Minerals Separation joined T. J. Hoover in applying for a British patent to use compressed air, and in that patent they themselves emphasized the difference between this method of introducing air and that described in patent 835,120. Therefore the Judge concludes that "the step of the process 'agitating the mixture until the oil-coated mineral matter forms into a froth,' meant the novel *air-entraining* agitation which the patentees disclosed, and did not cover the novel *air-releasing* agitation which the defendants disclosed." This is a notable pronouncement. It is not so much out of accord with the majority opinion as at first sight appears, the main difference being that the Court's decision is based largely on the use of the Pachuca and the pump, a modification of the pneumatic method now no longer in use at Miami, whereas the minority opinion recognizes that this particular modification was non-essential. Both opinions support the contention that the Callow cell does not infringe the method of agitation described in patent 835,120.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Manufacture of Cyanide in America

The Editor:

Sir—The Slogan 'Made in America' appeals patriotically to everyone who has the welfare of this country at heart, and every effort should be made to promote and foster all industries that can earn success without penalizing other industries no less important. Throughout the western United States the matter of cyanide is of importance to many mining companies, and it is regrettable that the supply of this necessary chemical is not sufficient to meet the demand. At the present time prices being paid range from about 30c. to \$1.20 per pound. The factors favorable to the starting of an industry in any new country are those that guarantee sufficiently low cost of material, also a steady demand for the finished article, adequate scope for a large output, abundance of experienced labor, and efficient management. Cheapness of power is also vital. The cheapest raw materials procurable are necessarily waste products from other industries, and in this matter the older countries have the advantage, and this is especially true when considering the manufacture of cyanide. Investigations of the scope for the industry reveal that in the United States and Canada the consumption of cyanide is quite large, although the advancement being made in the flotation method will tend to retard an increase in the demand. Details of the manufacture of cyanide on a commercial basis are not matters of public information, but descriptions of the main points are available in standard works such as Le Clerc's 'Cyanide Industry Theoretically and Practically Considered.' Here are descriptions of no fewer than 78 different processes for the manufacture of this chemical, indicating that, no matter what may be the handicaps, lack of variety of means available from which to make a selection is not one of them. It is interesting to know that the gold mines of the British Empire have been assured of an adequate supply, and also that in this era of high costs the price to all mines with contracts is the lowest that it has ever been. The Cassel Cyanide Co. of Glasgow, Scotland, after a venturesome and checkered career, has reached the distinction of being the largest producer of cyanide in the world. Founded originally as the Cassel Gold Extracting Co., Ltd., its primary object was to develop a gold-extracting process, invented by H. R. Cassel, and patented June 24, 1884. The process is described in the patent application as one for separating metals from ores and alloys, especially those of an auriferous character, by means of a solution yielding nascent chlorine under the action of an

electric current. The merits of the process eventually became a subject of fierce controversy. Charges were made that it belonged to the 'gold from sea-water' variety, and the climax was reached when the inventor suddenly disappeared. Disappointed but not discouraged, the directors engaged John S. MacArthur, then holding a responsible position with the Tharsis Copper Co., to investigate the situation, and if possible relieve them from an embarrassing position. He did so by offering a process invented by himself and the brothers Forrest on May 14, 1889. This consisted in subjecting finely comminuted argentiferous ores to the action of a solution containing a small quantity of a cyanide. This is particularly interesting in view of the fact that the process originally intended for the treatment of argentiferous ore was applied only after a long time for that purpose on a commercial scale. The rest of the history of the Cassel company is similar to that of nearly all patent-owners. First, there were demonstrations of the efficiency of the cyanide process in the treatment of gold ores. Then followed plant installations in New Zealand and South Africa, followed later by installations all over the world. Demands were made for prohibitive royalties from users. These brought forth the usual crop of prosecutions for infringement, legal complications, favorable judgments alternating with those that were adverse, with a finally depleted treasury, company re-organization, and general dissatisfaction. Early in the career of the company the directors realized the importance of manufacturing cyanide in co-operation with their policy of pushing the development of the process, since the ruling price of the chemical was then 60c. per pound. A small factory was erected and arrangements entered into with industries from which the raw material could be obtained on advantageous terms. The prohibitive royalty for the use of the cyanide process, however, scared away prospective customers and the outlook became hopeless. A change in the administration gave rise to a new policy. The idea of collecting royalty, even in countries where the patent was upheld, was abandoned, and the efforts of the concern were directed toward developing the manufacture of cyanide. Antagonisms gave place to hearty co-operation and mutual help. This was the starting-point in the company's success. Mine operators bought the Cassel company's cyanide, and received the benefit of their technical experience. A good article was made and supplied at a price then considered reasonable. Business expanded rapidly, handsome profits were made, and a large cash reserve fund accumulated. In August 1914 about 70% of all the cyanide used in the British

Empire was, like so many other things, made in Germany. Stocks were low, and the Cassel company found itself confronted with the task of keeping British gold and silver producers in operation. That that task has been met successfully is a matter of congratulation alike to the company and to the Empire, as serious interruption in the production of the precious metal might have exerted an adverse influence on the prosecution of the War.

Although the Cassel company in later years has been highly successful, the history of many other cyanide manufacturing concerns does not yield such pleasant reading. During the last quarter of a century the vast strides made in gold and silver mining through the introduction of the cyanide process all over the world, as well as the demand arising from fumigating orange trees, has called into existence at least half a dozen new cyanide manufacturing concerns in Great Britain alone. Some of these companies obtained contracts from mines for supplies covering long periods at fixed rates, but practically every one of these new ventures met financial disaster. Liquidators' reports showed that lack of previous experience had proved costly, that several mistakes had been made for which remedies were needed, that the cost of raw materials had advanced, and that the market price for cyanide had declined. Small quantities of cyanide are manufactured spasmodically by some British gas companies when the quantity of waste by-products greatly exceeds the demand of more profitable markets. A few chemical works also produce cyanide on a limited scale, generally as an adjunct to the manufacture of other cyanide compounds, such as ferro and ferri-cyanides. The Cassel company owes its vitality primarily to having owned and developed the process, and to receiving, at the commencement of its manufacturing career, a high price for its product by which it made large profits, and extended the scope of its operation without increasing its capital, but its success in recent years appears to be due to sound financing, to associations with co-ordinate industries from which could be obtained the necessary cheap raw material, and finally to the great advantages accruing from experienced management.

From what little information is available on the manufacture of cyanide, it is evident that the most economical conditions of operation are absolutely necessary to make the industry pay. In deciding on a location for plant, the factor of transportation must receive first consideration. Thus, in gold and silver mining, the bulky material is the ore, which, looked upon as raw material, is used in quantities out of all proportion to that of supplies required for extracting the metal in a marketable form, and the cyanide accordingly must be brought to the ore. In cyanide-manufacture a situation for a plant should be selected in the neighborhood of abundant cheap raw materials, and of other elements necessary for production.

The three essential materials are sodium, carbon, and nitrogen, the last mentioned being necessarily in such a

state that it will combine with the other two elements to form the compound NaCN . In Europe, at least two of these three elements are obtainable from the waste by-products of other industries and are therefore cheap. It would appear that the United States has reached a stage where by-products that can be classed as waste are available in commercial quantities, and if these materials are utilized, and a study of cyanide manufacture made, there would appear to be no reason why this substance should not be produced for home consumption at prices on a par with those existing in Britain.

Cobalt, Ontario, May 11.

JAMES A. McRAE.

The Nature of Chromic-Iron Deposits

The Editor:

Sir—In your issue for April 21 is an article on 'The Nature of Chromic Iron Deposits,' by Samuel H. Dolbear. Mr. Dolbear's explanation of the origin of chrome deposits is probably correct for a large proportion of such occurrences, but there are many bodies of chromite of commercial importance that are undoubtedly fissure-fillings in the ordinary sense. There are many such in California, particularly in the northern part of the State. For example, in Del Norte county is a series or belt of fissure-veins running north and south through a large mass of serpentinized peridotite. These veins have the conventional characteristics of true fissures. The filling is tale and selvage with little or no quartz, and the ore occurs in the form of lens-shaped shoots. There are areas or zones in the belt in which the lenses are high-grade chromite, other areas in which the lenses are magnetite, and still others in which they are pyrrhotite and bornite. These last have been worked in past years as copper mines. The different ores are not entirely separate, because the chromite contains a small proportion of copper and iron minerals, and *vice versa*. Such deposits could hardly be formed by magmatic segregation as described by Mr. Dolbear. The copper ore was found to be unprofitable below a depth of 500 ft. The chrome ore was worked to about the same depth in places, and the mines were closed because of the cost of transportation to market. The principal chromite deposits in that district belong to the Tyson Chrome Co. of New Jersey. Similar occurrences of chromite are found in Siskiyou county, California, and have been worked recently.

JOHN B. PLATTS.

Hawthorne, Nevada, May 18.

MAYARI STEEL, made from the Mayari iron ores of Cuba, has been attracting increased interest. The ores contain nickel and chromium, and consequently form a natural alloy, which possesses greater hardness, tensile strength, and higher elastic limit than nickel steel, and also has a slightly greater elastic ratio and elongation. Below a tensile strength of 150,000 lb. per sq. in. the Mayari steel shows a greater reduction of area than ordinary nickel steel.

LONGITUDINAL SECTION OF THE BLACK OAK MINE, TUOLUMNE COUNTY, CALIFORNIA

The Black Oak Mine

By W. H. STORMS

This mine, in Tuolumne county, California, is half a mile south-west of Soulsbyville and is operated by the Black Oak Development Company. It was discovered in 1878 and has been worked almost constantly for twenty-three years. It is one of the most important and profitable mines in California. In the original group were several claims, but the company has since acquired large additional acreage, some of which is good agricultural land. The principal workings and mine buildings are on the Black Oak claim. The shaft is sunk on the vein and has reached an inclined depth of over 1800 ft., the lowest level being 1750. The vein has a somewhat varying strike, but is always a few degrees east of north. The dip, which is westerly, is variable, the extremes being 35 and 90°, averaging about 70° from the horizontal. The country is generally called granite, but the rock varies from place to place. In the middle portion of the developed ground, for a horizontal distance of over 1000 ft., the rock consists chiefly of quartz, feldspar (both orthoclase and plagioclase), and an abundance of hornblende, while mica is scarce. At both the northern and southern ends of the mine-workings, however, biotite is abundant, and quartz is an unimportant constituent. The rock presents all of the phases peculiar to the granitic areas of the Sierra Nevada foot-hill region.

Dikes of dark-green fine-grained diorite are numerous, particularly in the north half of the mine-workings. These dikes have a prevailing north-east strike, and stand at high angles. Some of them cut the granite in other directions, and the greater number appear to be older than the vein, or at least, to antedate the ore deposition,

though there are exceptions. An effort to determine whether the granite had a strike in any common direction, disclosed the fact that such sheeting as could be identified had a strike in various directions, the most important being a few degrees west of north. East and north-east strikes were also observed. The region is one of much disturbance, which may be considered as contributing to the existence of the ore-bearing fissures.

The Black Oak vein varies in width from a seam to about 16 ft. It is said that in the old workings, above the 750-ft. level, it widened to 20 ft. Usually the hanging wall is well defined, but occasionally the ore is 'frozen,' and in some places the wall is rough and irregular. The vein exhibits a splicing-tendency, the ore occurring in overlapping wedges and lenses, with here and there a branch into the wall-rock. Several of these have been followed by drifts, but have usually proved disappointing at a short distance from the principal plane of fissuring. The ore is that common to the larger veins in granite, consisting of quartz impregnated with metallic sulphides, pyrrhotite being by far the most abundant. Pyrite and chalcopyrite also are present, though generally subordinate to the pyrrhotite. Galena and sphalerite occur more sparingly. Some of the iron sulphide is light colored, and is probably marcasite. All of these sulphides are auriferous, or, at least, are associated with gold, though an abundance of sulphides in the ore is not infallible evidence of high gold-content. The assay value of the ore ranges from \$2 to over \$100 per ton. The mill heads frequently assay from \$50 to \$80 or more per ton. One large stope averaged over \$12 per

ton; another returned more than \$23 per ton. Many tons of high-grade ore was shipped to smelters.

The structural features of the Black Oak vein are of interest. Several faults are exposed in the mine-workings, but only two are important, the others being of small displacement. The first fault discovered in the mine was cut years ago in the upper levels and it has been found on each succeeding deeper level that has been driven far enough to reach it. This fault has been named by the miners, 'the Slide.' Its strike is known only where exposed in the mine-workings in the vicinity of the vein, which it intersects at a low angle. The vein strikes 10 to 15° east of north, and the Slide strikes 15° more to the east. It also dips easterly at about 45° while the vein dips west. On each level where this fissure has been found it appears as a thrust or reverse-fault, that has displaced the vein and pulled the severed ends 50 ft. apart forming a band or zone along the plane of intersection of these two fissures, that, when plotted on a vertical longitudinal section, has a dip of 30° to the north. This zone of displacement usually contains some ore, due to 'drag' rather than to original deposition in this part of the fissure, for the rest of the 'Slide' fissure, so far as known, is not ore-bearing.

In the northern part of the mine is found what is known as 'the fault.' This is a normal dislocation that intersects the vein on its strike at an angle of 50° (strike N. 65° E.) The dip is southerly, but is variable, being 80 to 90° on the 1600-ft. level, and about 65° on the 800 and 1100-ft. levels. It was first found on the 800-ft. level 500 ft. north of the shaft. On each level it was found intersecting and displacing the vein in the same manner, but always at a point farther south. The former management of the property, in earlier years, did not understand the geological problems here presented, and whenever the fault was reached drifts were run on it on the supposition that it might be the vein, but no ore was found on the fault-fissure. Drifts were also driven straight ahead, on the course of the vein in the hard granite, but nothing was found in that direction either. After a time the mine was closed and it remained idle for some years. It was under the present manager, Roger C. Knox, that the vein was re-discovered by cross-cutting to the west through hard granite. This cross-cut was run normal to the strike of the faulted vein and in 110 ft. reached the fissure once more. The vein here has much the same appearance as south of the fault, but strikes more to the westward than south of the displacement. The fault-zone is several feet wide, consisting of two approximately parallel main fissures with numerous subsidiary fractures between. The granitic material is much crushed and altered, and in places has a gouge-like appearance, though this occurs locally.

This fault is the most important disturbance discovered in the mine, but its position, strike, and dip having been determined on every level between the 800 and 1800-ft. levels, it is no longer a source of uneasiness in planning the development, though it entails additional expense in running the cross-cuts through the granite,

which is exceedingly hard. Each cross-cut is over 100 ft. long. North of the fault, which for many years had been thought to end all profitable mining in that direction, the present owners have stoped a body of ore 500 ft. long, over 500 ft. high, and from 2 to 16 ft. wide. This body of ore yielded a handsome profit. Below the 18th level for its full length it is still unstopped. In addition to this ore-shoot, the entire region of mineralization south of the fault has possibilities below this present lowest level of the mine.

As an example of the somewhat erratic occurrence of ore in the Black Oak mine, a long drift had been driven on the vein south of the shaft, on the 10th level. Some stoping had been done above but had been discontinued. South of the shaft, 630 ft., at a place where the vein was thin, a small quantity of ore was found in the back. A raise at this point showed decided improvement at a height of 40 ft. Three days later a face of ore 4 ft. wide was exposed 30 ft. long that assayed nearly \$20 per ton. The ore, however, continued upward only a few feet and work there was discontinued. The 10th level remained idle thereafter until the fall of 1914 when a winze was sunk 545 ft. south of the shaft, following a small stringer of ore, to a depth of 60 ft. A drift south at a distance of 100 ft. from the winze cut the downward extension of the ore that had been found nearly a year previously in the raise above the level. The ore in the raise lay immediately under the smooth hanging wall, but where a drift was started north on this shoot, the ore left the wall and extended into the foot, departing 25 ft. from the wall in driving 100 ft. The ore was not particularly rich, but with the best ore in the new vein always opposite the richer ore next to the hanging-wall vein. This unusual condition continued for 250 ft. The ore extended northward to a point 84 ft. from the shaft, where the foot-wall vein abruptly turned to the east and the ore disappeared. The foot-wall vein dips 55° west, while the hanging-wall vein dips 70° west. The two veins unite 90 ft. below the 10th level, and contrary to the common belief that the union of two veins should produce a bonanza, the junction of the veins in this instance was disappointing, as the ore was neither abundant nor rich. A raise was driven above the 13th level beneath the winze on the 10th level, to search for this new shoot, and it was cut 100 ft. above the 13th level where rich ore was found, continuing without interruption to the 10th level.

This new and unexpected ore-shoot, discovered where no ore was supposed to exist, was stoped 400 ft. high and 300 ft. long, and produced \$250,000. It illustrates the vagaries of veins of ore in granite. It is interesting to note that this ore-shoot, as well as all others in the Black Oak mine, occurs entirely under the hills, and that little or no ore has been found beneath Curtis creek or any other depression that crosses the vein.

At the north end of the mine, on the 15th level, the fissure has been followed a long distance beyond the north end of the ore-shoot north of the fault. It is persistent, though small. It shows no ore, and the formation has changed. For some distance the fissure cuts through

a dike of diorite, then enters a hard silicious rock, resembling alaskite, dark-gray in color, due to inclusion of some dark-colored mineral. On passing beyond this unusual rock, no trace of which was found elsewhere on the surface or underground, the fissure continues in the granitic rock, which here contains much biotite as well as hornblende, but with only a few quartz granules. Prospects for ore in this direction appear discouraging.

The metallurgy of the Black Oak ores was for years a serious problem and thousands of dollars were spent in experimenting. The old company succeeded finally in obtaining a high extraction, but was unable to recover the gold and silver from the sludge. The filter solved the problem. The ore now is crushed by stamps in cyanide solution, the pulp going to Dorr classifiers; the fine to Dorr thickeners and the coarse to a tube-mill, where it is ground to 200-mesh; this also goes to thickeners, and with

of this area, the Black Oak vein striking through it in a north-south direction, and the west branch of the Soulsby vein entering the ground near its north-east corner. The long drift on the 1500-ft. level of the Black Oak mine runs several hundred feet under the Imperial area, but is protected in this by extra-lateral right. The Imperial company has had numerous pits sunk on outcrops upon its property, and is now sinking the Harry and Landers shaft on the Black Oak vein, where a good prospect has been discovered. Nothing has yet been done on the Soulsby vein in this property, and further prospecting will be necessary before any extensive or permanent development is there undertaken. The Soulsby mine has been one of the most profitable mines in the State, having a record of \$6,000,000 produced, a large part of which was profit.

Joining the Live Oak on the south is the Yost ranch,

THE BLACK OAK STAMP-MILL AND CYANIDE PLANT

the fine from the first thickeners goes to three Pachucas connected in series. From the Pachucas the solution goes to an Oliver filter. Clarifying and precipitation-presses do the rest. The 20 stamps crush 80 tons per day. The actual saving averages 97%, and sometimes exceeds it. A new compressor has lately been added to the surface equipment; also a saw-mill having 5000 ft. daily capacity. The tailing is now being impounded.

At the south end of the Black Oak property and forming a part of it is the Live Oak claim, where rich ore was discovered at the surface many years ago. A shaft was sunk there on a vein two feet wide, the ore running about \$25 per ton in gold. After an idleness of years the mine was re-opened and some very good ore mined. The 10th level of the Black Oak has been extended into the Live Oak, and good ore discovered on that level also.

The property of the Imperial Mining Co. adjoins the Black Oak on the north and comprises a tract of 160 acres, being what was formerly known as the Landers ranch. There are numerous veins traversing the granite

on which is the Junction mine, where a shaft, said to be 300 ft. deep, was sunk in 1896 to 1898. Some very good ore was found in a small shoot 70 ft. from the surface, but the development as a whole proved disappointing, and work was discontinued. The vein is thought by some to be the southerly continuation of the Black Oak-Live Oak vein, but if this be so there must be a displacement of 200 ft. or more, due to faulting. This has not been determined. From the Junction vein, which strikes north-south, there are several veins branching from the main fissure. These branches all have a north-east or south-west strike, some on the east side and others on the west side of the principal vein. These branches in places carry rich ore, \$100 per ton and over, but the veins as a whole are too low-grade to be mined profitably. One of these veins is separated by horizontal floors with spaces an inch or two wide that are filled or partly filled with clay and crushed fragments of quartz. The material between these floors always contains gold, far above the vein rock itself in value.

Fixation of Nitrogen

Both for plant-food and for the manufacture of explosives it is necessary to produce nitrogen in a 'fixed' form. Nitrogen is readily fixed by the action of certain bacteria, known as nitrous and nitric bacteria (*Nitrosomonas* and *Nitrosococcus*), which are present in soils in all parts of the world. These are responsible for the nitrification of soils without which plant-life would dwindle and disappear; but intensive agriculture, with removal of the products for consumption elsewhere, depletes the soil of its fixed nitrogen, and this must be replaced by fertilizers. It has been assumed by some investigators that nitro-organisms were responsible for the accumulation of nitrates in the desert of Tarapacá, Chile, but it is doubtful whether this agency has been more than feebly contributory to the formation of the great deposits of sodium nitrate which are found in that region. It is more probable that it is a result of direct combination between original magmatic nitrogen occluded in the volcanic flows and tuff and the nascent hydrogen evolved in the formation of magnetite as one alteration product in the rock, as pointed out by De Kalb (M. & S. P., May 6, 1916). In the United States there has been almost complete reliance upon these natural Chilean resources, while great efforts have been made in Europe to develop artificial means of fixing nitrogen to an economic stage. This has been accomplished in various ways. The United States Government last year appropriated \$20,000,000 to establish a hydro-electric plant for producing fixed nitrogen. We have dawdled as is our wont, and the plant is not even yet under construction. Meanwhile great plants are being erected abroad, and recently one was started in Sweden to utilize the Birke-land-Eyde process, and to be ready within the current year. We might have had similar works in operation had the business been conducted with military concentration of purpose. Instead, we have squabbled over the merits of the constituencies bidding for the establishment of the nitrogen pork-barrel in their midst, and have listened to complaints that we were lacking in knowledge of the economies of the various processes, while the Teutonic hindering policy was insidiously introduced under the guise of learned scientific quibbling.

The cyanamid process, however, has been successfully developed at Niagara Falls, and is more readily available for introduction into new plants, where cheap hydro-electric power can be obtained promptly, than any other method. The accumulated experience in its manufacture in this country is also strongly in favor of its immediate application. Frank S. Washburn of the American Cyanamid Co., one of the ablest electro-chemists in the world, has cogently argued for the instant application of this process by our Government, and the proposal made is a patriotic one, involving no high-priced monopoly. For the benefit of those who may not be familiar with the cyanamid process it may be stated that calcium carbide is first made from lime and carbon in the electric furnace. The carbide is then finely ground and the

powdered material charged into another electric furnace of special design where it is maintained at 1000° C. Pure dry nitrogen, produced either by the copper oxide or the Linde process, is then passed over the hot carbide and is there absorbed. Starting with a carbide containing about 80% of that compound, from 80 to 90% of the theoretical quantity of nitrogen will be absorbed. The product is a grayish-black mass of cyanamid (CaCN_2) mixed with calcium carbide and lime. It contains about 20% nitrogen. If this be treated with superheated steam the nitrogen is disengaged from the cyanamid in the form of ammonia, which can then be oxidized by the Ostwald or other processes to nitric acid for use in the manufacture of explosives. Sodium cyanide may also be made from cyanamid by fusing it with common salt.

Mr. Washburn's comments, given at length in the *Oil, Paint and Drug Reporter*, afford interesting comparisons between the competing processes for the fixation of nitrogen, which are of great significance in view of our extraordinary need of this vital resource. He says: "The arc-process requires for the fixation of a unit of nitrogen between five and six times as much power as is required by the cyanamid process. For the production of 180,000 net tons of concentrated nitric acid per annum, 540,000 continuous horsepower is required by the arc-process and 100,000 continuous horsepower by the cyanamid-process, which at \$100 per horsepower installation-cost is the difference between \$54,000,000 and \$10,000,000. The total installation-cost of the arc-process is excessive compared with the installation-cost of the cyanamid-process, particularly where the cost of developing power is not extremely low. With the cost of power-installation at the modern American figure of \$100 per continuous horsepower on the switchboard, a plant for 180,000 net tons of concentrated nitric acid per annum by the arc-process would cost \$80,000,000, and under the same conditions a plant for the same capacity by the cyanamid-process would cost \$30,000,000. For the production of fertilizers alone the disproportionate cost of plants of equal capacity is much greater than indicated by the figures above for the production of nitric acid. Concentrated nitric acid by the arc-process, taking the installation-cost of power at \$60 per continuous horsepower on the switchboard, costs per ton to produce one-third more than by the cyanamid-process. This disproportion is, of course, correspondingly greater where the cost of power-installation is \$100 per continuous horsepower. The disproportion in the cost of producing equivalent quantities of nitrogen in the form of fertilizer alone is greater than for nitric acid. Even with power at what would be an abnormally low figure in the United States, namely, a \$10 operative cost per continuous horsepower on the switchboard, the pound of nitrogen produced by the arc-process costs for power alone as much as the total cost of the pound of nitrogen by the cyanamid-process, including power, materials, labor, interest, amortization and depreciation. The Haber process does not seem to have found an advocate in the present controversy, as far as known. The process is protected by United States patents."

The Miami Appeal

Minority Opinion of the U. S. Circuit Court of Appeals, Philadelphia

BUFFINGTON, J., dissenting:

Putting aside all minor incidents, this case in my judgment, involves one broad, basic and far-reaching question, and that is whether any and all advance and improvement in the sphere of air flotation in mineral recovery for the next few years shall be subjected to what will practically be a blanket claim for any use of air as a flotation agency.

The claim which we are asked to construe and apply is for:

"The *herein* described process of concentrating ores, which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of one per cent. on the ore), agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation."

I say, putting aside all minor incidents, for it is perfectly clear that if all kinds of air flotation and all kinds and degrees of agitation are covered by this claim, the infringement of the defendants is self-evident by their use of compressed air which produces some agitation and causes air flotation. To my mind, and for reasons I shall now discuss, this claim should not be awarded this sweeping scope which will paralyze the subsequent development of a great art.

Now, if any broad right to monopolize all air flotation with a limited use of oil but an unlimited use of agitation exists, it arises by virtue of a contract made between these patentees and the government, and that contract is embodied in the claim of the patentees, made by them and conceded by the government, the other of the contracting parties, and the consideration for that claim is the required statutory disclosure made by the patentees:

"* * * of the manner and process of making, constructing, compounding, and using it, in such full, clear, concise and exact terms as to enable any person skilled in the art * * * to make, construct, compound and use the same * * *, and he shall particularly *point out* and *distinctly claim* the part, improvement, or combination which he claims as his invention or discovery."

Turning now to the patent itself, which has been held valid and described by the Supreme Court as "patentable, as new and original as it has been found useful and economical," let us inquire first what was the new thing disclosed, for therein we have the consideration for the claim; and second, what claim was allowed in consideration of such disclosure. This line of approach, is, to my mind, imperative, first, because while an invention

may be broader than a claim, a claim can never be broader than an invention. Finding from this claim that it concerns two things, oil and agitation, we must necessarily turn to the specification and there ascertain what was the new disclosure as to oil and agitation. In substance, it was the disclosure of a process in which a hitherto unused minimum of oil and a hitherto unused maximum of agitation were used. Each of these disclosures was summed up by the Supreme Court in these words:

"The process of the patent in suit, as described and practised, consists in the use of an amount of oil which is 'critical,' and minute as compared with the amount used in prior processes 'amounting to a fraction of one per cent. on the ore,' and in so *impregnating with air* the mass of ore and water used, by agitation—'*by beating the air into the mass*,' as to cause to rise to the surface of the mass, or pulp, a froth, peculiarly coherent and persistent in character, which is composed of air bubbles with only a trace of oil in them, which carry in mechanical suspension a very high percentage of the metal and metalliferous particles of ore which were contained in the mass of crushed ore subjected to treatment. This froth can be removed and the metal recovered by processes with which the patent is not concerned."

It will thus be seen that, first, the quantity of oil, secondly, the character of agitation, and, thirdly, the resultant froth, constituted the disclosure. Apart from the authoritative statement of the Supreme Court as to what was the invention of these patentees, which of course controls us, it is clear both from the proofs, the physical facts and a general knowledge of the art, that such was the case, and that this discovery is bottomed on agitation—the new kind of agitation disclosed—which made possible a new extension of well-known properties and capacities of oil into fields oil had not reached by any previous methods of agitation. And it follows that if agitation of maximum character is the dominating factor that made possible the use of a minimum of oil, that claims which specify the use of oil and of agitation must not be read in a way that ignores the new and disclosed agitation, which was not only the only specific agitation, but the only generic agitation the patentees disclosed. For it is perfectly clear that if the art of air flotation today had stopped where the disclosure of this specification left it, that the only method of air flotation would be the agitation disclosed in the patent. The specification does not purport to disclose or to make use of any newly discovered property of oil. Let that fact be clearly understood. That oil had three qualities was well known prior to this patent—first, that oil had an

affinity for metal particles; secondly, that the oil covering the metal was of infinitesimal thinness; and, third, that oil has no affinity for and will not coat gangue. Such being the known action of oil, viz.: its affinity and its capacity for thus thinly coating it and for not coating gangue, it is manifest that whenever oil, gangue and metal particles are mixed only a minute quantity of oil was needed to coat and actually did coat the mineral particles. The larger quantities of oil used were not needed or used to coat, but to float, the minerals. These facts are proved by the testimony of Sulman, hereafter quoted and alluded to in the House of Lords opinion, referred to later as an agitation which "assists the process of minute quantities of oil reaching minute particles of metal." But while the small quantity of oil used as a metal covering was a fact, the significance of that fact was not recognized in the preceding practice, for the manifest reason that in such art there was no use of oil alone for metal covering purposes, but it was used for the double purpose, first, of oil covering, and second, oil flotation. When, therefore, the patentees disclosed a process in which the oil necessary for flotation was dispensed with, the requirement of a small amount of oil for purely coating purposes became at once apparent and assumed a new significance. This was referred to by the Supreme Court when, in distinguishing it from the prior art, it said:

"The small amount of oil used makes it clear that the lifting force which separates the metallic particles of the pulp from the other substances of it, is not to be found principally in the buoyancy of the oil used, as was the case in prior processes," etc.

From these considerations it will be seen that oil required and used for covering or coating the mineral particles was precisely the same in quantity and function in prior practice and the practice of this patent. But what did happen was that the violence and duration of the agitation brought more particles into contact with oil than when the agitation was less violent. What, then, was the disclosure? This is clearly shown by the patentees in their specifications, where they show the *nature of their improvement* by contrast with the prior practices of the Cattermole patents. These proofs show that the present discovery was made while working on the process disclosed by Cattermole and the specification recites its relation to Cattermole. Turning, therefore, for information to Cattermole's patents, I find Cattermole's process was one where oil was used for the double purpose, viz.: First, such small quantity as was necessary for metal particle covering; and, second, such large quantity as was necessary for metal particle flotation. I say "for metal particle flotation" advisedly for, while the process finally ended in the metal particles finding their way to the bottom and the gangue to the top, yet as a necessary precedent step to making the metal particles go to the bottom, they were first floated upward, so as to enable them to *there* nucleate or agglomerate in such numbers that their combined weight overcame the buoyant capacity of the oil and they sank to the bottom of the

vessel. These several actions are set forth by Cattermole, as follows:

"The invention depends upon the application of the following facts: First, when a mixture of powdered metalliferous matter and gangue is treated with oil suspended in water—that is to say, in emulsion—the oil has *more or less selective action and will coat the particles of metalliferous matter in preference to the particles of gangue*, while the particles of gangue will be wetted by the water; second, if the water which is mixed with the oil is acidulated with mineral, fatty, or other acid the *selective action of the oil will thereby* be rendered more marked and decisive; third, if the proportion of oil is kept within reasonably low limits (differing in different cases, according to the nature of the mineral to be treated and the consistency and nature of the oil) and if the mixture of water, oil, metalliferous particles, and gangue be *thoroughly agitated* the metalliferous particles which have become coated with oil will adhere together and form granules, which granules, partly by reason of gravity and partly on account of their bulk, as compared with the individual grains of gangue, will offer ready means for separation in an upcurrent separator, a jig, or other similar appliance."

At this point it should be noted that as the patentees, in order to explain their disclosure, by reference make the Cattermole patent part of their specification, as the agitation used by the patentees was a step in the Cattermole process and the Supreme Court found the patentees used and disclosed "an agitation greater than and different from that which had been resorted to before," and also that "the extent of the agitation of the mass had been increased as the experiments proceeded until the series of the Gabbett mixers, fitted with the usual baffles, were speeded at from 1,000 to 1,100 revolutions per minute," an inquiry into the character of the new kind of agitation used and disclosed by the patentees becomes essential to a due understanding of the disclosure made. As recognized and stated by the Supreme Court, this agitation consisted in the patentees speeding up a Gabbett mixer to ten or eleven hundred revolutions per minute. The extent of the agitation of the mass had been increased as the experiments proceeded until, as stated by that Court, the "series of Gabbett mixers, fitted with the usual baffles, were speeded at from 1,000 to 1,100 revolutions per minute." It is apparent that this tremendous agitation speed through a mushy substance like pulp could only be reached by some special appliance impelled by powerful mechanism since no ordinary paddle mechanism could stand the strain and furnish the power to meet such a requirement. We accordingly find that this was done by the patentees speeding up to hitherto unused speed the device known and used in Cattermole's process. Instead of seeking to move the whole pulp mass by rotating paddle pressure on the whole mass—a thing which, owing to the length of the paddle required would be impossible, Gabbett, as shown by his patent No. 444,345, segregated a part of the pulp. This segregated part alone he moved by paddles and

thereby set up a centrifugal force in the pulp in such segregated section, and thus made the centrifugally moving pulp itself the agency for moving the pulp on the outside of this inner dividing vessel. His device was built in two forms, one of which expelled the pulp at the top and the other at the bottom. Referring to the top expelling device, shown by Figure 1, which, as we shall hereafter see, these patentees necessarily declined to use, its operation is as follows:

"A is a conical shell, having internal ribs A² and mounted on a shaft B, by which it is suspended within the vessel or tank C, containing the liquid to be acted upon, the shaft being carried at its upper end by a bracket D and guided by a bush or stuffing-box E on the cover of the vessel C. Assuming this vessel to be charged with liquid to the level indicated and the shell A to be rotated by suitable gearing, such as indicated at F, then the body of liquid within the shell being carried round with the same by means of the ribs A¹, the centrifugal force will cause the liquid to rise along the inclined inner surface of the shell and to be ejected into the surrounding liquid when arriving at the upper edge thereof, while at the same time the pressure of the surrounding column of liquid in the vessel C will cause fresh quantities of liquid to enter the lower end of the shell A to make good the quantity discharged at the top. Thus a continuous circulation and consequent mixing of the liquid will be effected, as indicated by the arrows."

That is, the machine discharged at the top. Its paddles, being submerged in the segregated pulp, it could not beat in air. But neither Cattermole nor the patentees who adopted Cattermole, used the top *outlet* type of Gabbett's device above described, but did use the other or top *inlet* type shown in Figure 9, although both moved the pulp in the same way, but in opposite directions.

Selecting the top inlet or cone type shown in Figure 9 of Gabbett's two forms, although both machines and agitators were, with the exception named, counterparts, there was a functional advantage in the top inlet type used which was vital to the working of the present patentee's process. And that there was a functional disadvantage in the top outlet type which would have been fatal to the working of their patent will, for reasons hereafter stated, be made clear. The only point now made is that the agitation, and the only agitation which the patentees disclosed as embodying the agitation of their process, was an agitation of one of two particular kinds, namely, one where they utilized their agitation power on a small zone of *segregated pulp*, and where, for functional reasons, as we shall hereafter see, they applied such agitation to this segregated pulp as it was traveling in one direction, that is, downwardly. At this point we recall, as before stated, that Cattermole's object was to nucleate or agglomerate into a mass the individual oil-coated mineral particles, or, as summarized by the Supreme Court, "agglomerating the oil-coated concentrate into granules heavier than water, so that they will sink to the bottom of the containing vessel." As stated in the patent, "the more oil is used the larger, softer and

less numerous the granules." It was in the use and experimentation of this process that the discovery of the patent in suit was made, and these experiments were duly reported (see Vol. 4, p. 22 and following) from time to time. From these reports it will be seen that the agitator used was of the cone-shape, upper-intake type already described and shown in Figure 9. By March, 1903, they found the value of both violent and protracted agitation; and that such protracted and violent agitation was effective to coat the mineral particles with oil. "Somewhat violent agitation is now required for a few minutes; the time being dependent upon the efficiency of the agitation, and varying from two to five or eight minutes, whereby the oil is released from the gangue and attaches itself exclusively to the mineral." Later, that is, in March, 1914, when a speed of 988 cone revolutions was reached, and the effect of agitation effecting air-fotation was noted, where, under the head of "Flotation factor used," it was said:

"* * * the coarse sands when passing through the last two mixers were allowed to be *beaten well with air* by keeping the liquor low in the mixers and using fast agitation, with baffles in. The concentrates were then found to be floated up in the outcast if only a general up-current were used."

The italicising of the words "and" and "up," the phrase "beaten well with air" and "fast agitation," show that the significance of violent agitation and the entraining of air was in the path of experimentation following the basic feature of the subsequent disclosure of the specification. In March, 1905, under the head "Influence of peripheral velocity of cone"—and it must not be overlooked that "cone" was the word which described the inlet top (Fig. 9) of the Gabbett mixer—it was said, "An increase in the peripheral velocity of the cone causes a decrease in the time required for granulation, a point being reached after which this decrease is slight." From this entry it will be seen that increase of agitation was still regarded as and was the factor which was leading toward the discovery afterwards made and disclosed in the specification. In the next report both the speed and the type of Gabbett's agitation is again emphasized by contrasting:

First.—The low speed of the Gabbett as useless;

Second.—The Gabbett cone mixer alone and with baffles added as an additional agitation agency;

Third.—The inability of a centrifugal pump speeded higher than a Gabbett mixer to furnish the agitation requisite.

These points are all outlined in said report as follows:

"The influence of the speed and type of agitation becomes a factor of great importance to our recent experiments. Speeds of rotation (with a small Gabbett) varying from 3 to 500 revolutions per minute, proved almost useless. This shows the necessity of high speed agitation."

Continuing, the report said:

"We then made a series of baffles which were placed

in the Gabbett and which were 'solid.' *i. e.*, they occupied the *greater free space* of the Gabbett vessel from the glass sides up nearly to the working surface of the cone. They were found to be disadvantageous as they gave *too violent* agitation, and set up large eddy currents in front of each baffle, greatly reducing rotation speed of the liquor in the Gabbett and adding *water friction* to such an extent to the rotating cone, that the power required to drive the latter was more than doubled. On replacing these solid baffles by the *ordinary type of thin rod baffles*, the granulation period was much improved, and the power consumed in driving the cone fell again to the normal."

This, to our minds, shows that although the baffles increased the agitation, they precluded the kind or quantity of agitation desired. Manifestly the stoppage and delay of the pulp in eddies caused by the baffles, stopped the steady and more frequent passage of the pulp through the cone and this lessened the amount of agitation in the segregated zone where the air was beaten in.

Continuing, the report adds:

"We have also carried out a series of experiments with a small centrifugal pump in place of a Gabbett, to determine whether this gives a better form of agitation than the cone. * * * The following figures were obtained by Mr. Leechman yesterday in comparison with the Gabbett, and show the latter to be distinctly preferable to the centrifugal pump experiments. We may say the centrifugal pump used was only a small one, having about a 4½ to 5" chamber, but it was speeded up to about 1,200 revolutions per minute. The pump, therefore, had a considerably higher peripheral speed than the Gabbett used in parallel tests."

From this it will be seen that by a process of elimination it was becoming evident that the agitation desired was only obtainable on a cone or top inlet Gabbett mixer, and that the violent agitation by solid baffles and by the higher speed of a centrifugal pump were both objectionable.

In the light of subsequent events, it is quite evident why this was the case. In the first place, the top inlet or cone Gabbett mixer, by the rapidity of revolution, formed a hollow air chamber around the shaft, into which air was drawn down and was there beaten by the paddles into and aerated the pulp. It is also clear that if solid baffles were used on the sides of the outer chamber, the rapid flow of the pulp would be measurably stopped and it could not pass as often through the cone, and therefore was not subjected to as much air beating as when the baffles were not used as manifestly all the air beating took place in the cone. And lastly, while in the Gabbett mixer the revolving paddles in the cone were able to strike and beat the air into the surrounding pulp, it is evident the blades of the centrifugal pump, *being necessarily wholly immersed in pulp*, had no contact with air or an opportunity to beat air in. In other words, by its blade submerging, the centrifugal pump had no more power or opportunity to beat air into the blade-enveloping pump than would have been the case had the paddle blades of a Gabbett mixer with a top outlet (see Figure

1) whose blades would also be wholly immersed in the outflowing stream, been used.

It will here be noted that as the centrifugal pump was the sole form of agitation used in this particular stage of the experiments, and as it was discarded by the experimenters, that, tested by the acts of these patentees, no logical grounds existed for their counsel now planting themselves on the position that the pulp lift of a centrifugal pump is the air agitation of their disclosure and claim.

In the next report, March 16, under the head "Influence of the percentage of oil," we find the effect of oil reduction is noted:

"The effect of diminishing the percentage of oleic acid is to alter the type of oiling; the higher percentages producing granules, and the lower froth. Six per cent. of the oleic acid on the mineral is sufficient to form good granules without much froth. * * * 0.62% oleic acid on the mineral is insufficient to form any granules and nearly the whole of the mineral comes to the surface on stopping the cone, as froth."

It will be thus seen that it was agitation, and agitation of a selected type and speed, that gradually led up to the May 3, 1905, report, where the invention was definitely recorded. And when this was done it was accredited to the agitation indicated. That report says:

"We beg to hand you herewith a statement of the new method of oil concentration which we have been engaged in investigating and working out in detail, for the purpose of your forwarding to Mr. Courtney and his staff in Australia. It will be best to start with a short statement of the principle on which the process depends. In determining the lowest limit of oleic acid which could be employed in granulating, it was found that granulation practically stopped at a range of about 0.5% of oleic acid on the mineral (60 mesh Broken Hill), in an acid circuit somewhat below 1% in strength. A certain amount of black mineral froth was, however, noticed as a result. On successively decreasing the amount of oleic acid below 5% it was found that whereas granulation ceased there was a growth in the amount of mineral float-froth under these conditions, and that the production of such float-froth appeared to reach a maximum when about .1% of oleic acid on mineral was used. This froth on collection was found to consist of oiled mineral slimes *mechanically holding more or less coarse* (oiled) mineral particles, the froth carrying between 70 to 80% of the total mineral present in the charge." * * * "The froth produced is not due to any action of the acid circuit upon traces of calcite present in the ore, *i. e.*, not to the liberation of any gas in the charge by means of the dilute acid employed in the circuit. It has been located, on the contrary, to the aid introduced by the Gabbett cone during agitation, the air attaching itself to the oiled mineral slimes and to a large proportion of the coarse mineral particles, although both these materials can only be coated with an infinitesimal amount of oil, *i. e.*, oleic acid. That the formation of froth is due to air inclusions during the agitation, and not to carbonic acid or sulphur-

etted hydrogen is proved by the following experiences:"
 * * * "The plant consists of a series of Gabbett mixers fitted with the usual baffles, and speeded at from 1,000 to 1,100 revolutions per minute as regards the conc. These Gabbett mixers are identical in every respect with those used for the original Cattermole process. * * * The operations are therefore summarized as follows: *Gabbett agitation* in the usual way with .1% oleic acid"—

thus themselves coupling with their invention at its birth the name of Gabbett and Gabbett agitation, which they now seek to avoid.

This terse and complete summary of the discovery in "*Gabbett agitation* in the usual way with .1% oleic acid," is also the summary of all that is set forth in the specification of the patent in suit, and further and other than "*Gabbett agitation* in the usual way with .1% oleic acid" the long specification discloses no method or suggestion of other agitation, and gave none to the art. Such specification starts with reference to the Cattermole patent from which we have quoted, No. 777,273 and 777,274, and states that in the former—

"Oil varying from four per cent. to six per cent. of the weight of metalliferous metal present is agitated with an ore pulp so as to form granules which can be separated from the gangue. * * * We have found that if the proportion of oily substance is considerably reduced—say to a fraction of one per cent. on the ore—granulation ceases to take place, and after vigorous agitation, there is a tendency for a part of the oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum."

Such was the discovery the patentees embodied in the two claims here in issue, viz., Claim 1:

"The herein-described process of concentrating ores which consists in mixing the powdered ore with water, adding a small proportion of an oily liquid having a preferential affinity for metalliferous matter (amounting to a fraction of one per cent. on the ore), *agitating the mixture until the oil-coated mineral matter forms into a froth, and separating the froth from the remainder by flotation.*"

And Claim 12:

"The process of concentrating powdered ore which consists in separating the minerals from gangue by coating the minerals with oil in water containing a fraction of one per cent. of oil on the ore, *agitating the mixture to cause the oil-coated mineral to form a froth, and separating the froth from the remainder of the mixture.*"

It will be observed that these two claims do not themselves cover any complete, workable process of concentration disclosed in the specification, but are separate steps or elements in the process of workable concentration described in Claim 3, which, in addition to the above elements, includes the elements of acid and heat. And that the extract quoted above, embodied in Claims 1 and 12, was not a complete concentrating process, but merely certain elements or steps of it, is made clear by the patentees, for, after reciting that "there is a tendency for a

part of oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum," they add:

"This tendency is dependent on a number of factors. Thus the water in which the oiling is effected is preferably slightly *acidified* by adding, say a fraction of one per cent. up to one per cent. of sulphuric acid or other mineral acid or acid salt, the effect of this acidity being to prevent gangue from being coated with oily substance, or, in other words, to render the selective action of the oil more marked. * * * Again, we have discovered that the tendency for the *oily substance to disseminate* through the pulp and the rapidity with which the metalliferous matter becomes coated is increased as the pulp is *warmed.*"

It will thus be seen that the workable concentration process which the patentees gave the art, was one in which the "flotation of mineral particles" was dependent on a number of factors, viz., first, Gabbett agitation; secondly, .1% of oleic acid; thirdly, .1% sulphuric acid, and fourth, heated pulp. And the workable process embodied all these four elements used in the method of working the invention which the patentees necessarily showed in compliance with the statutory requirements that they "shall file in the Patent Office a written description of the same, and of the manner and process of * * * using it, in such * * * exact terms as to enable any person skilled in the art * * * to use the same," suggests that they regarded all four elements as constituting their workable process and, indeed, they attribute to heat the permeating and rapid coating of the minerals with oil.

Complying with the statutory requirement, the patentees say:

"The following is an example of the application of this invention to the concentration of a particular ore. An ore containing ferruginous blende, galena, and gangue consisting of quartz, rhodonite, and garnet is finely powdered and mixed with water containing a fraction of one per cent. or up to one per cent. of a mineral acid or acid salt, conveniently sulphuric acid or mine or other waters containing ferric sulphate. To this is added a very small proportion of oleic acid (say from 0.02 per cent. to 0.5 per cent on the weight of ore). The mixture is warmed, say, to 30° to 40° centigrade and is *briskly agitated* in a cone mixer or the like, *as in the processes previously cited*, for about *two and one-half to ten minutes*, until the oleic acid has been brought into *sufficient contact* with all the mineral particles in the pulp. When agitation is stopped, a large proportion of the mineral present rises to the surface in the form of a froth or scum which has derived its power of flotation *mainly from the inclusion of air-bubbles introduced into the mass by the agitation, such bubbles or air-films adhering only to the mineral particles which are coated with oleic acid.*"

It is urged that this is but a sample method of showing how their process was workable. But the sample element consisted in the particular treatment given to a particular character of ore. It was not a sample of one

of many possible kinds of agitation for the kind of agitation applicable to all kinds of ore was concededly of one sort, namely, as therein stated—"briskly agitated in a cone-mixer or the like, as in the processes previously cited." And the testimony of those who made the discovery and made the disclosure shows that the way and the only way they discovered and disclosed, was a definite kind of agitation and that this definite kind of agitation made their disclosed process workable. Indeed, that maximum of agitation and minimum of oil, increase of agitation and decrease of oil, were axioms in this process is made clear by the proofs. As the amount of oil was decreased, the amount of agitation had to be increased. In that regard, Sulman, one of the patentees, Vol. 1, p. 53, says:

"The first requisite of any oil concentration process is to obtain efficient contact between the oil and the mineral and suitable methods must be employed to effect this. Where the oil is in large relative quantity to the mineral *violent agitation is unnecessary* and may be very harmful. With decreasing proportions of oil more vigorous agitation or mixing *is necessary to ensure such efficient contact of oil with the mineral particles*. The agitation may, therefore, be said to be roughly proportioned to the work to be done in bringing about contact between large or small quantities of oil in regard to the mineral."

His evidence (p. 54) is that in the Gabbett mixer, of the cone type, he first saw produced the froth of the specification:

"The apparatus that I first saw the agitation froth produced in as described on the specification referred to was the ordinary Gabbett apparatus consisting of a vessel with rotating cone and with suitable baffles. The cone was rotated at a high rate of speed, about 1,000 revolutions per minute."

The use of the ordinary speed of the Gabbett mixer to effect the intermingling of the oil with the mineral particles, and the use of superadded speed for the purpose of entraining air and producing froth, is made clear by the testimony of Picard, another of the patentees. Thus (p. 109), in answer to the question:

"Q. In carrying out the process which the patent in suit purports to disclose, is there anything distinctive about the mode of agitation of the oiled pulp as compared with the agitation used in applying the Cattermole Process, wherein the purpose is to granulate and precipitate the valuable mineral?"

Picard says:

"In actual fact the same apparatus was employed for both purposes during my connection with the experimental work on the two processes. In the patent in suit it is *more essential to beat in air*, which is not an important point, and *rather to be avoided*, in the Cattermole process, where the object *was only* to mix the various ingredients, air not being one of them."

And he adds (p. 110):

"We already knew from the first test that the cause was due to reducing the quantity of oil much below that hitherto employed, and observation of the froth clearly

indicated that the air which had been beaten in played an important and *essential* part in the production of this new phenomenon. I presume that further investigation work was carried on, but in my opinion, the invention may be said to have been completed after that first operation. * * * I had no idea prior to this, that by reducing the quantity of oil to the limits which were used in this experiment that such a result would be obtained. I, of course, knew that air would float mineral, previously oiled, but it was not anticipated by me hitherto that this particular result would be obtained if *air were beaten in*, in the manner in which it was done in making this test."

John Ballot, the third patentee, also emphasizes (Vol. 1, p. 118) this "intentional beating in of air" caused by violent agitation, where in answer to the question:

"And when you saw the work in progress from March 1, 1905, onwards, as referred to by you in your answer to question 29, was this the first occasion upon which you had been informed as to the use in an oil flotation process of the *intentional beating in of air* for the purpose of promoting flotation,"

He says:

"The *intentional beating in of air* to produce or promote the flotation of froth which was developed by that process was certainly not known until the fact had been actually discovered by using a very small quantity of oil, say .2 or .1 per cent., and agitating it for a certain time, and then leaving the mixture to stand that the whole froth rose to the surface. By 'discovered' I mean until the experiments had established the fact that this extraordinary phenomenon was every time reproduced by using the small quantity of oil, *violently agitated*, and then leaving it to stand, when the mineral rose to the surface in the form of dense froth."

He adds:

"We considered it established and that the principal cause of flotation, or *perhaps the entire cause of flotation*, was *due to air beaten* into the pulp, assisted, of course, by the other agents."

Indeed, the discovery of beating air by agitation into the pulp as the ground-work of the discovery and therefore of the resultant disclosure, is summed up by the witness Ballantyne (Vol. 1, p. 225), in the words:

"After *violent agitation in such a way as to introduce air into the pulp*, the agitation lasting several minutes, the pulp was brought to rest immediately a coherent and persistent froth rose to the surface. Although I was closely familiar with all the earlier processes of ore concentration in which oil had been used, * * * the production of this agitation-froth was to me little short of a miracle."

In this development it will be seen that Mr. Ballantyne makes the violent agitation of the cone mixer the basic step in these words.

But not only was the testimony of these witnesses that this air-beating or air-entraining agitation was the agency which produced a froth of a hitherto unknown type, but we have the authoritative view of the Supreme

Court that the *lifting force* of the bubbles is to be found not in the quantity of oil used, but in the maximum of agitation, "greater than and different from that which had been resorted to before." We think the agency of this air-beating-in agitation as the functional cause of air flotation, is made clear by the Supreme Court. In that regard that Court says:

"The small amount of oil used makes it clear that the lifting force which separates the metallic particles of the pulp from the other substances of it is not to be found principally in the buoyancy of the oil used, as was the case in prior processes, but that this fact is to be found, chiefly, in the buoyancy of the air bubbles introduced into the mixture by an agitation *greater than and different* from that which had been resorted to before and that this *advance* in the prior art and the *resulting* froth concentrates so different from the product of other processes make of it a patentable discovery as new and original as it has proved useful and economical."

In quoting and approving the decision of the House of Lords, 27 R. S. C., the Supreme Court alluded to the dual functional capacity of the patentees' agitation: first, as a mixer of oil with the mineral particles (the function of Gabbett agitation at normal speed), and secondly, the formation of air cells by air entraining (the function of Gabbett agitation at abnormal speed). The extract thus quoted with approval from the English decision, is:

"They (the patentees of the *Agitation Froth Process* of the patent in suit) are not promoting a method of separation which had been before described, but they are engaged upon a new method of separation. Instead of relying upon the lesser specific gravity of oil in bulk they rely upon the production of a froth by means of an agitation which not only assists the process of *minute quantities* of oil reaching *minute* particles of metal, but *forms a multitude of air cells*, the buoyancy of which air cells forming around single particles of the metal, floats them to the surface of the liquid."

And that agitation of a particular kind, and not agitation of any kind, was the disclosure of the specification, is shown by Dr. Liebman, who says:

"I believe that 500 or 600 revolutions are quite sufficient for the Cattermole process (metal sinking). But I believe that at least 1200 revolutions per minute are *necessary* for the process of the patent in suit in the same apparatus."

From the above review, it is clear that the basis of this invention was agitation, and of agitation of a particular type and power, and that such type and kind of agitation gradually led to the further discovery that all oil except the minimum required for mineral coating could now be dispensed with. That the invention cannot be based on the use of a minimum of oil alone is clear, for the stress laid on agitation in the specification and its presence as an element in the claim here in issue, forbid any such holding, and the further fact that a claim based wholly on the use of a fraction of 1% of oil for coating minerals was abandoned during the prosecution of the patent, to wit: "The process of concentrating powdered

ore which consists in separating the minerals from gangue by coating the minerals with oil in water containing a fraction of 1% of oil on the ore, and recovering the oil coated minerals."

Seeing then that no change occurs in the character of the oil itself, in the amount required to coat the metal particles or the affinity of the particles when coated, it follows that the essence of this patent lies in the agitation by which this low percentage of oil is made available. Now what was the nature of this agitation? It had a number of characteristics:

First—It was produced by machinery of high power operating on mechanism revolving at high speed. The mechanism was a special type, *i. e.*, a *top-inlet* or *cone* Gabbett mixer which embodied certain features, each of which was necessary to the successful working of the invention disclosed; a, the application of the mixer to the pulp was confined to such restricted zone of the *pulp* as was inside the cone; b, to this cone-restricted zone the air had access; c, the speed of the agitation was raised to a hitherto unused point; d, the air in the chamber was by the speed of the agitator beaten into the pulp segregated in the cone; e, in addition to high speed, time was required, the agitator being revolved from 2½ to 10 minutes before the entrance of air appeared in froth; f, the *agitation* was of such novel, individual and inventive character as to warrant the grant of a patent; g, the *agitation* was of such special type and speed that the froth it produced was also of a new type, or as the Supreme Court said, "utterly different from any froth known before."

But because the claims here in controversy use the word "agitation," without description or limitation, it is argued that the term should be used in a broad, generic sense and cover any and every agitation which results in the air flotation of mineral coated particles. Put into practical commercial application, this means a monopoly of the principle of air flotation of oil-coated minerals, with the one exception, namely, where 1% or more of oil is used. To our mind, this use of the literalism and verbiage of this one word agitation to foreclose this whole great controversy, loses sight not only of the spirit of the patent law, but also of the principles on which this contract—for a contract with the Government is what this claim is—should itself be interpreted, for in construing that contract we must construe it as a whole, that is, the claims plus the specification, and not the claims minus the specification. We must also consider the claims in the light of the evolution of experiment that led up to the discovery and consequently to the disclosure.

It is argued here that no sort of agitation is specified in the specification, that the phrase or idea of beating in air is not even mentioned in the specification; that there is no mention of any specific form of agitation, and that therefore there is no qualification or limitation to be given to the type or kind of agitation. But this loses sight of the fact that the patent is based on the Cattermole process, and that that process and the patentees'

used a Gabbett mixer, and when the word "agitation" was used in the specification it referred to what the patentees had used in making their discovery, and was well understood by persons versed in the art; and when they spoke of the production of froth by agitation they meant precisely what they reported in their experiments, to wit:

"The froth produced is not due to any action of the acid circuit upon traces of calcite present in the ore; i. e., not to the liberation of any gas in the charge by means of the dilute acid employed in the circuit. It has been located, on the contrary, to the *air introduced by the Gabbett cone during agitation, the air attaching itself to the oiled mineral slimes and to a large proportion of the coarse mineral particles, although both these materials can only be coated with an infinitesimal amount of oil, i. e., oleic acid.* That the formation of froth is due to *air inclusions* during the agitation, and not to carbonic acid or sulphuretted hydrogen is proved by the following experiences:"

It is quite evident not only that this was the precise word and the disclosed sort of "agitation" they had in their minds when they disclosed their discovery. Moreover, we think that courts and Judges have held this was the meaning of "agitation." In passing upon the validity of the patent, the Supreme Court explained what the patentees' invention was, and defined the agitation of that discovery as "beating the air into the mass." This beating of air into the mass by the Gabbett mixer being the sense in which that word was used in the specification, and no disclosure or suggestion of any other agitation being made, the burden is certainly on the patentees to show that when the word "agitation" was used in the claim it meant anything else than the agitation disclosed in the specification, to wit, that of the Gabbett mixer or its substantial equivalent. For the word "until" in "agitating the mixture *until*," aptly described the "two and a half to ten minutes" of the directions of the specification during which a Gabbett mixer was to be operated before the froth was produced. In so holding, we do not minimize, belittle or underrate the very important discovery these inventors made. But the great discovery they disclosed was based on two facts, oil of a certain amount and agitation of a certain kind. The quantity of oil was less than 1%. The agitation was by beating in the air until a froth came. That was the extent of their discovery, their disclosure and their claim. Within those limits they are entitled to protection. Beyond that the art has a right to progress and improve.

So regarding the claim, we turn to the defendants' plants, as to first of which, namely, the one in operation when the bill was filed, there can be no question. It is simply a replica of the plaintiff's process; used as a Gabbett mixer, as did Hyde in the case in the Supreme Court, and so far as it is concerned, infringement and an accounting should be decreed. But as to the defendants' second plant, I cannot agree that the claims in question cover it. I shall not enter into a detailed description of

its working, but at present restrict myself to saying that the basic feature of the defendants' process is the sub-aeration of the pulp through the agency of compressed air. There is no air expansion as an agitation agency in plaintiff's process. They beat no air into the pulp; they introduce compressed air into the pulp and avail themselves of the instant expansion of that air to form a different kind of bubble from that of the patentees, and they get a different kind of froth. And the crux of the case may, as we view it, be stated in this way: If the defendants were applying for a patent for concentrating ore, which consisted in sub-aerating a mixture of ore and a fraction of one per cent of oil through the agency of compressed air, would such process be anticipated by the plaintiffs? The test of that question is not whether the product of two processes is the same, but whether the steps of the two processes are substantially the same. Addressing ourselves to that question, I have reached the conclusion that the defendants' process approaches the problem in a wholly different line from the patentees, and while the result is the same, that result is reached by steps or means acting in a different way and by a different method. Physically the defendants' method substantially and functionally consists in the liberation of air under light pressure, seven pounds compression, into the pulp mixture. Physically, by the turn of a stopcock this light pressure is turned on and instantly aeration and bubble forming begins and agitation follows. The physical difference between the two systems is as striking in its way as it would be if a person standing on the stern of an ocean steamer and seeing the maelstrom caused by the one hundred a minute revolutions of a screw, and should be told that these revolutions, the screws themselves, the shaft and the ship's great engines, could be taken out of the ship and their places supplied by a tank of air under mild compression. And yet that is just what these defendants have done. They have eliminated, not one hundred, but a thousand revolutions a minute of the Gabbett mixer; they have eliminated the shaft, couplings and power machinery which was necessary to actuate this. And for it they have substituted the stopcock of a tank filled with air under light compression. Defendants have eliminated such a distinctive element of plaintiff's process that it was patented. The physical difference between the means employed is well illustrated in this way: Suppose the owner of the Gabbett agitator were to sue the defendants for infringement by the use of a compressed air apparatus, could an expert be found so rash as to even suggest that the two were substantially equivalent? Not only are the two not mechanical equivalents, but it is evident that in the two processes the Gabbett mixer and the compression tank work on wholly different principles. The Gabbett mixer uses agitation to beat the air in, in order to thereafter produce bubbles—and that only after several minutes' work produces bubbles, and these bubbles only rise after the several minutes' agitation goes on. In other words, in plaintiff's process bubbles are the product of agitation. In the defendants' practice the

expansion of the air itself on its release from compression, at once creates bubbles and the instant rise of these bubbles to the surface at once sets up agitation. In other words, the defendants' bubble causes agitation, while in the patentees' agitation causes bubbles. In the one there is a gentle agitation of the fluid caused wholly by the expansion of air when released from compression. In the other there is no expansion of the air, it is simply beaten into the mixture by the action of the arms of the Gabbett mixer. In the plaintiffs' process the agitation forms the air cells and only after several minutes' physical exertion; in the defendants' the air, on its release from compression, by its own inherent power, forms the cell and forms it instantly. It has been suggested that in defendants' process the air is shot into the mixture like a bullet from a gun and that there is no difference between shooting air into a mixture with a gun and beating it in with a paddle. But it is manifest that the defendants' practice is not the shooting in of a violent air-blast, but is in allowing air under slight compression to escape from such slight compression at the bottom of the tank. To have the compressed air strike the top surface of the pulp would not lead to any bubble introduction, and consequently to no subsequent agitation by arising bubbles, for such bubbles as would be formed would already be near the surface. It will thus be seen that the introduction of compressed air is necessarily made at the bottom of the pulp vessel, and it is also apparent that no such *sub-air* introduction which characterizes the defendant's process could be effected by the Gabbett beating in of the air, for in such case the moving blades of the mixer would have to be wholly immersed in water, and as we have seen heretofore, such immersion forbade the use of the top-outlet form of Gabbett agitation shown in Fig. 1. These differences in form and principle, the difference between a hurricane and a zephyr, the spread between the maelstrom action of a swift-moving mechanism and the bubbling, seeping action of air released from compression at the foot of a tank, and then in the case of the Callow cell oozing or seeping its way between the threads of a canvas, are so different in degree of violence and mode of action that one would naturally expect some difference should evidence itself in their product. And such is the case. In the defendants' process the bubbles rise at once to the surface, but they are so frail that they absolutely require the continuous support of other bubbles. For in case the air is shut off below and the upward bubble stream stops, those on the surface at once disintegrate. The defendants' bubbles are ephemeral; they are matured at birth; and, like all such creations, lack self-sustaining power. On the other hand, the plaintiffs' bubbles evidence themselves at the surface in a froth which is only formed after from 2500 to 11,000 revolutions of the mixer ($2\frac{1}{2}$ to 10 minutes \times 1000 to 1100 revolutions), but when so gradually formed are so self-sustaining that they last for days and are so tough that they support a shovel. If the production of such froth by such a protracted and violent agitation was a contribution of inventive and novel worth to ore con-

centration, and apart from all authoritative decision that is our estimate of the goal it reached, then for another to reach that same goal without making the tough, persistent, shovel-carrying froth and without using the thousands of revolutions of powerful machinery, absolutely required to produce it, is also a contribution of inventive and equal worth to ore concentration. And the best evidence of its worth, of its simplicity and of its effectiveness is the fact that the plaintiffs themselves use it and concede its superiority. Concededly valuable as sub-aeration is, it is certain the ore concentration art never would have had it if we were dependent on the plaintiffs' patent to give it to the art. Not only did the patent in suit not disclose it; but if anything, their disclosure pointed away from rather than to the probability of the use of compressed air. Thus in their specification they take pains to avoid the imputation even of using gas as a flotation agency, and *ex majore cautella* give notice that "it is to be understood that the object of using acid in the pulp according to this invention is not to bring about the generation of gas for the purpose of flotation thereby," a statement the Supreme Court referred to as evidencing that their work tended not in the line of introduction of gas, but "to the presence of the air introduced into the mixture by the *agitation* which had been resorted to, to mix the oil with the particles of crushed ore."

Indeed, that the use of compressed air with their concentration process was not in the patentees' concept is strikingly shown by the fact that had they had any such use in view of the power of compressed air to do the work of the Gabbett mixer, their suggestion of the possibility of its use was almost challenged by the use to which they suggested it could be put to in the second and third spitzkasten where no mixing or separation was required. They there say:

"An alternative method for the recovery of any sunk oiled metalliferous matter which may be deposited in the second and third spitzkasten is as follows: The products suspended in circuit liquor are removed from the spitzkasten and placed in a vessel in which they are submitted to an *additional pressure of air or other gas* of from, say, one to two atmospheres or over. On relief of such pressure the bubbles of air or other gas *so generated* throughout the mass at once sweep to the surface thereof all the metalliferous matter in the form of a froth which can be separated as before. This idea is not claimed broadly in this case, but forms the subject-matter of an application filed by us on January 9, 1906, Serial No. 295,326."

Of course, whatever ideas they had on the subject were embodied in another application and offered no basis for a claim in this patent, but even this suggested use of compressed air as a flotation agent to these experienced men suggested to them no use of that agency in the process of this patent. It remained for some other engineer, in this case the defendants' experimenter, to discover and disclose it. This view is emphasized by the fact that five years after this patent was applied for and two years after it became the owner of it by assignment, the plain-

tiff joined with one Hoover in applying for a British patent for such use of compressed air. In that patent the patentees themselves emphasize the points we have made, saying:

"This method of introducing the gas may have three functions: (1) The gas may bring about the necessary agitation of the mass. (2) The gas being in a state of very fine division, is effectively brought into contact with every mineral particle, thus *clearly differentiating the process* from that of the patent where the mechanical stirrers caused the agitation and thus *preceded bubbles*, while here *bubbles preceded and caused agitation*. In the patent in suit the mechanical action of the stirrers, kept up for ten minutes, brought about air being brought into contact with the mineral particles, while by the subgaseous process, the gas being in a state of fine division through seeping through the canvas, is as said above, 'brought into contact with every mineral particle.'"

The fact that the present plaintiffs, five years after the grant of the patent, joined Hoover in taking out this patent, in itself shows that it then regarded the sub-air process as one not covered by the patent in suit, and may well cause a court to hesitate to give a construction to the patent in suit which is at variance with the plaintiffs' conduct in taking out this Hoover patent.

To me it seems clear that the field of discovery the patentees disclosed was not the broad principle of air flotation, for concededly that principle was known before. What they did disclose was an original method of using the broad principle of air flotation in a particular way. That method was by beating air into pulp with a minimum of oil. They showed how the beating in of air could be effected, and they showed a novel froth product as a result of this beating-in process. In their process air was the product of agitation and not the agitating agent. In their process bubbles did not appear until protracted agitation was ended. Not only was it produced by agitation, but it did not appear until agitation ceased. It will thus be seen that air was in no way an agitation agency in the plaintiffs' process, in its specification or in its claims, but the agitation disclosed therein was wholly the physical agitation of an extraneous mechanical process. Now, this occupancy of the field of air flotation, novel, useful and inventive, the plaintiff disclosed and should be awarded. But by occupying this part of the field, the process of entraining air by mechanical beating in, the plaintiff did not foreclose all further advance in air flotation. Air flotation, as a recognized principle, was known before this patent, and by discovering one way to utilize that principle, the patentees did not bar all other ways of making use of that principle. If they had discovered the broad principle of the capacity of oil to coat minerals and to reject gangue; if they had first discovered the coating of air bubbles with oil; if they had first shown that oil-coated minerals and oil-coated bubbles would unite and rise to the surface, we could regard them as first-comers into a newly discovered field, and as entitled to make all further progress in that art servient to those who created it. And while this has

been done in some notable instances, it is nevertheless true that even great and notable steps in a great art can be disclosed by patentees without blocking all further progress in that field. In that regard we are admonished by the later rulings of the Supreme Court in patent causes, which began with *Westinghouse v. Boyden*, that even such a great invention as the instantaneous stoppage of every car on a great freight train, an invention which is at the bottom of the movage of tonnage today, did not bar other inventors from showing other means of using air to accomplish the same result. And such holdings as *Westinghouse v. Boyden* and the like, seem to us the true principle which should govern the administration of the patent law, namely, giving full protection to the full limit of the disclosure made, and refusing to extend that limit so as to bar further advance by others. Applying that principle to the present case, I would hold that the step of the process "agitating the mixture until the oil-coated mineral matter forms into a froth," meant the novel air entraining agitation which the patentees disclosed and did not cover the novel air releasing agitation which the defendants disclosed. In accordance with these views and in support thereof I am constrained to record my respectful dissent to the opinion of the Court.

PRELIMINARY ESTIMATES based on practically complete returns made to the U. S. Geological Survey, by domestic refiners of platinum, indicate that in 1916 approximately 488 oz. of domestic crude platinum (about 74% metal) was refined, producing 172 oz. platinum, 84 oz. iridium, and 113 oz. iridosmine, and that 10,118 oz. of South American crude platinum, about 88% pure, was refined. The platinum metals produced by refining crude placer-platinum, of both foreign and domestic origin, amounted to 8943 oz. platinum, 235 oz. iridium, 199 oz. iridosmine, and 18 oz. palladium. Refiners of copper matte and gold bullion report a production from foreign and domestic material of 2556 oz. platinum, 100 oz. iridium, and 2746 oz. palladium. About half of this was produced from domestic materials. The total production of new platinum metals in 1916 was about 11,500 oz. platinum, 335 oz. iridium, 200 oz. iridosmine, and 2765 oz. palladium. The scrap platinum metals sold in the United States in 1916 amounted to approximately 49,400 oz. platinum, 980 oz. iridium, and 2000 oz. palladium.

ALUMINUM alloyed with 10% calcium makes a metal of superior qualities, lighter than aluminum, and particularly desirable for castings to be used in automobiles and aeroplanes. These castings machine well, are free from brittleness, and take the minutest impressions of the mold. Alloys of copper, tin, or zinc, with aluminum are softer and heavier than the calcium-aluminum alloy, and are less resistant to corrosion. The calcium also neutralizes the tendency of the aluminum to oxidize. It does not decompose in water, and can be remelted as readily as pure aluminum. This alloy is the discovery of Hugh S. Cooper of Cleveland, Ohio.

Conditions in Mexico

By AN OCCASIONAL CORRESPONDENT

According to the Government press, Mexico re-entered the 'constitutional' era on May 1, the "un-constitutional" era having lasted since Huerta's usurpation in February 1913. The inauguration of Venustiano Carranza was marked by an extra national holiday, and this coming on Tuesday of the same week as the regular holiday of Saturday, meant a week of loafing for a large part of the peon class. Among the many festivities of the week in Mexico City was a sham-battle by a brigade of school-boys with real guns. Unfortunately, the first volley resulted in the wounding of a great many boys by the bullets of the 'blank' cartridges. Some say that the accident was due to some disgruntled general, who had the ball-cartridges mixed in for the purpose of discrediting Carranza, but American miners will be more apt to believe the theory that it was merely a typical example of Mexican carelessness, exhibited in the munition department of the army. The national Congress assembled on April 15 in Mexico City for the first time since Huerta's *coup d'état* in October 1913. A fortnight previous the national capital had been transferred back to Mexico City, from Querétaro, where it has been since Carranza's departure from Vera Cruz in September 1915. Like the 'constitutional assembly,' which closed its work in Querétaro on February 28, the new congress is a carefully hand-picked body of Carrancista partisans. In many districts there were several independent candidates; but no matter how many votes he got, a non-official candidate (where not counted out in the local returns) was easily disposed of by the credential committee at Mexico City. The large vote cast, so widely heralded in the foreign press as a sign of popular enthusiasm, was really caused by a decree which penalized the failure to vote by the loss for a year of citizenship-rights. As Carranza was the only presidential candidate, he could not fail of election, no matter who voted, and he was, of course, 'unanimously' elected. A curious feature of the election in Mexico City was the candidacy of Dr. Atl, whose campaign had to be conducted by his friends, as the Doctor was in hiding, due to his proscription last September. If elected, he proposed to appear and claim the legal immunity from arrest of a deputy, but luckily for the repute of the brand new constitutional machinery, it was not subjected to any such excessive strain, for Dr. Atl was ruled out in committee.

In Anglo-Saxon countries, the main object of parliamentary institutions is to control the public purse, but this does not hold in Mexico, since one of the first acts of the new congress was to grant 'extraordinary faculties' to the Secretaría de Hacienda, that is, the Treasury Department. This means that secretary Louis Cabrera can continue his irresponsible career and issue decrees concerning national finance, taxation, and expenditure, to suit himself and Carranza, without any reference to the congress. The looting of the banks of issue beginning last December, seems to be nearly completed, as

most of their vaults have now been emptied of their metallic reserves, and part of the process of liquidation it at present being conducted by the various Incantación commissions appointed by Cabrera. It seems probable that a large part of the ₧40,000,000 worth of gold bullion now being coined for Mexico as an 'international courtesy' at the Philadelphia mint, hails from these bank reserves, since it consisted largely in gold and silver bars. That this bullion proceeds from the Mexican bullion tax, as stated to the press by Cabrera, is physically impossible; because, though the normal Mexican output of gold is about ₧40,000,000, it has scarcely been a third of this for the past three years, while the bullion tax has only been 10% on the gross output.

Since December last the soldiers have been paid in coin at about the same rates that were prevalent under Madero, but the civil service has had to accept 50% of its wages in bonds, so that instead of real money it has received certificates of indebtedness; but from July 1, civilians will also be paid entirely in coin at the rates of 1912. When the Government was on a paper basis, from 1914 to 1917, it accepted American money for taxes at the rate of \$1 for ₧2 of Mexican gold, but since specie payments have been resumed it has found it profitable, especially in its collection of taxes from American miners, to artificially depreciate it.

THE SOUTHERN PACIFIC Co. played an important part in assisting the Pacific Coast to over-subscribe the Liberty Loan. Figures made public at the general offices of the company in San Francisco, show that the total amount subscribed by employees on the Pacific system alone reached \$1,319,000, which sum was pledged in 12 days after the call issued by President Sproule. Among the large individual Southern Pacific subscriptions were those of Mr. and Mrs. William Sproule, \$25,000; chief counsel Wm. F. Herrin, \$24,000; vice-president E. O. McCormick and family, \$10,600; chief engineer Wm. Hood, \$5000; claims attorney D. R. Sessions, \$5000; assistant chief engineer J. Q. Barlow, \$2000; vice-president and general manager W. R. Scott, \$2000; auditor T. O. Edwards, \$1100; A. D'Heur, manager of fuel-department, \$1000; Dr. F. K. Ainsworth, chief surgeon, \$1000; R. J. Clancy, assistant to the general manager, \$1000; superintendent of transportation G. F. Richardson, \$1000; H. P. Thrall, inspector of transportation service, \$1000; D. P. Kellogg, superintendent of motive-power at Sacramento, \$1000.

COAL-TAR CREOSOTE is largely used for mine-timbers, railway ties, and for timbers in situations exposed to conditions favorable to the growth of destroying fungi and bacteria. The toxicity of creosote to such growths is well known, but it has been demonstrated by C. J. Humphrey that maplewood creosote is from 2 to 4 times as effective. It kills the fungus-growths when used in dilutions as low as 0.1% of the creosote in an alkali emulsion. In this respect it is equal to beechwood creosote.

Automatic Skips in Shaft With Rope-Guides

By H. VINCENT WALLACE

The accompanying detail drawings show an automatic skip used successfully in the 2000-ft. shaft at Nueva Luz, Guanajuato, Mexico, standing the test of over 250,000 trips without failure to properly operate. This entire equipment was constructed in the blacksmith shop at the mine by an ordinary Mexican blacksmith and helper. It will be noted that the hook-levers that engage the skip-doors are keyed to the shaft, which is also keyed and set-screwed to the operating lever placed under the sloping bottom of the skip; the safety-link, therefore, when hanging over one hook, securely holds the other against its lug, in addition to the spring which keeps the centre lever at all times tense.

To empty the skip it was the duty of the top-man, first to drop the apron having high sides, this being attached to a counterpoise and provided with a short cable and pulley. Next the safety link is thrown back. The hoisting engineer then lowers the skip until the lever, by pressing on the apron, releases the hooks, allowing the load to be discharged into the bin. When the engineer raises the skip to disengage it from the apron the skip-door swings shut and is automatically locked by reason of the spring exerting the necessary pressure on the lever. If by any chance the top-man fails to drop the safety-link, the skip-tender is warned to check him before filling the skip at the shaft-pocket below, and the mine-record shows that the device was efficient even in

the hands of the Mexican workmen. The photographs accompanying this article show the skip in various posi-

DETAIL OF BALANCED DOORS

DETAIL OF SKIPS, SWINGING APRON, AND LATCH

tions. The balanced shaft doors are not claimed as an original idea, but were developed and the design prepared in detail from recollection of a pair seen in operation somewhere in Staffordshire or South Wales about 1889. Previous to this installation, it had been the custom to have two top-men, one on either side of the shaft, each operating one door. These, when closed, were in the form of an inverted V. One man then had to hook the bucket and direct its 'dump' as the engineer lowered it. On the bucket being discharged the two men again, with an expenditure of a good deal of power, opened the doors and allowed the bucket to be lowered into the shaft. In the event of lowering tools or other materials, one or the other of these men had to descend to the collar of the shaft. All this led to delay and caused extra expense. Moreover there were inverted V doors both at the collar of the shaft and at the dumping level above.

SWINGING APRONS ERECT, AND IDLE SKIPS ON PLATFORM

The balanced doors shown in the accompanying illustrations could be operated either by the top-man or by the hoist-engineer, although the drawing does not show the rods connecting with the hoist-house. These doors can be made readily in any ordinary mine-shop, the only parts required from a foundry being the properly calculated cast-iron counter-balance weights. It should be noted that the strap-hinges, counter-balance arms, and the 8-in. radius-levers, are all intended to be keyed and fixed in place with set-screws, the counterweights to be adjustable for the weight of the door and fixed at the correct distance with set-screws. It was found that one top-man could easily attend to both pairs of doors in the double-compartment shaft, as it required about 7 min. per trip. When the skips were hoisting waste or ore, the same top-man attended to the unloading apron and the safety-link, since it was found quite unnecessary to close the doors after making about 1000 trips; as not a particle of rock ever found its way down the shaft when a skip was being discharged.

SWINGING APRON AT MOMENT OF DUMPING

STRONTIUM is in limited demand at the present time for the manufacture of red-fire to be employed in signalling. The mineral celestite (SrSO_4) is preferred to strontianite (SrCO_3), and is worth about \$12 to \$14 per ton at Atlantic ports. Celestite exists in large deposits about 5 miles north-west of Austin, Texas, at Mt. Bonnell, the grade obtainable assaying 97 to 98% Sr SO_4 . It is found in many places rather abundantly in the Silurian limestones and dolomites. In series of lime deposits from the concentrated brines of inland seas, chemically precipitated lime (CaCO_3) will go down in advance of the strontium minerals, but the latter will precipitate ahead of the gypsum. Therefore strontium deposits are not infrequently found beneath beds of gypsum. Celestite is often disseminated in small aggregations along with limestone or with gypsum, but, owing to its relatively high specific gravity (3.95), it is amenable to concentration. A large deposit of celestite was recently discovered four miles north-east of Lavic station on the Santa Fe railroad, San Bernardino county, California.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

CRIPPLE CREEK, COLORADO

OVER A MILLION PAID IN DIVIDENDS THIS YEAR.—IMPORTANT NEW LEASES OPERATING WITH SUCCESS.

Sunday, June 10, was dividend day for stockholders of the Cresson Consolidated Gold Mining and Milling Company, and Golden Cycle Mining and Reduction Company. The Cresson dividend was at the rate of 10c. a share, amounting to \$122,000. The Golden Cycle dividend was at 3c. a share, making \$45,000, a total for the month of \$167,000.

With these distributions Cripple Creek corporations have paid stockholders in the first six months of 1917 \$1,312,941.42. The dividends of the so-called close corporations are not included in the foregoing sum.

The companies and dividends to date for 1917 follow: Cresson Consolidated G. M. & M. Co. (monthly), \$732,000; Golden Cycle M. & R. Co. (monthly, \$270,000; Portland Gold Mining Company (quarterly 3c.), \$180,000; Vindicator Consolidated Gold Mining Company (3c quarterly), \$90,000; Doctor Jack Pot Mining Company (1c.), \$28,441.42; Jack Pot Mining Company of Wyoming (1c.), \$12,500 Total, \$1,312,941.42.

The May production from the Acacia Gold Mining Company's South Burns mine, on Bull Hill, totaled about 250 tons, seven broad-gauge cars, with an average value of \$26 per ton. Shaft-sinking was in progress and production was necessarily curtailed. Between 7 and 10 cars of ore have been shipped from the mine since June 1.

Shipments were started on June 11 from the new three-compartment (Scott) shaft, on the Happy Year group of the War Eagle Consolidated Mines Company, on the southwest slope of Bull Hill. The ore is of milling grade and is mined from a shoot 110 ft. long, recently opened by a lateral from the 400-ft. level. Lessees are operating on two blocks of the War Eagle adjoining the Happy Year group, and are saving ore of milling grade.

Twenty-eight cans of concentrates, 18 cans from the Independence mill, below the ore-house at Stratton's Independence, and 10 cans from the Victor mill, on Battle mountain, were forwarded on June 11, by express from Victor to the Valley mill of the company, at Bruns, near Colorado Springs. This is a record shipment for any one day from the two plants. The ore concentrated had a gold value of \$2 per ton. During May, the concentrate cans had an estimated value of from \$800 to \$1000 each.

Shipments have been commenced from the Forest Queen, an Ironclad Hill property, under lease to Edwin Gaylord, formerly of Denver. A cave in the old workings, which occurred before Gaylord took possession, carried down and filled the slope between 600 and 450 ft. with ore worth from \$8 to \$12 per ton. Gaylord has equipped the shaft with a steam-hoist and 60 hp. high-pressure boiler and is hoisting this mill-ore with a skip, while development in the mine proceeds.

Illinois and Michigan capital, represented locally by Sam Cleverdon, is interested in a lease on the Nightingale, a Stratton Estate property on Bull and Raven Hills. Cleverdon is sinking a new shaft on the Raven Hill side of the claim, near to the Maggie claim of the Cresson Consolidated Company. Machinery will shortly be required.

Al Osberg, lessee of the Mable M., of the Gold Dollar Consolidated Gold Mining Company, closed a five-car shipment from the new ore-shoot recently opened up at the 500-ft. level

of the Mable M. shaft June 9. Osberg estimates this trial shipment at 2 oz. of gold per ton.

Company work at the 18th and 19th levels of the Golden Cycle shaft of the Vindicator Consolidated Gold Mining Company is producing a fair tonnage of a medium-grade ore, and making a large production in the deep levels of the Vindicator main shaft. The Hull City mine, after long idleness, is active under lease to Frank Seeley, a former district operator, now of Oklahoma. The mine is producing a milling-grade of ore.

The May production from the active properties of the United Gold Mines Company, the Trail, Bull Hill, W. P. H., and Damon mines, on Ironclad Hill, and the Silver Tip mine, Bull Hill, totaled 2500 tons of a gross bullion value of \$50,000. The Trail mine, with 3 sets of lessees, alone produced 57 broad-gauge cars and the W. P. H. mine 16 cars of ore.

A carload of ore from the Mountain Beauty mine, on Bull Hill, owned by the Mountain Beauty Gold Mining Company, and operated by lessees, Schoolcraft, Bulter & Co., brought settlement last week at the rate of 5.81 oz. gold, or \$116.20 per ton. A carload of second-grade ore was settled for at \$40 per ton.

The Granite Company, operating the Dillon mine on Battle Mountain, continues to load out from three to four cars of ore daily by team, but the overhead-tram is nearing completion and the cost of transportation will soon be reduced. Lessees on the Dead Pine, Monument, and Gold Coin properties of the company also are shipping steadily, the ore being consigned to the mill of the Golden Cycle Mining and Reduction Company, at Colorado Springs. Colorado City, as a corporation, passed out of existence the night of June 10.

The Strong shaft is being sunk to the 1550-ft. point. The mine continues to produce a high-grade ore. The Strong Company, a close corporation, is sinking the shaft, and a depth of 1550 ft. will shortly be attained.

Upraising from the 13th and 11th levels of the old Modoc incline, directly under the new vertical Frankenberg shaft, on the property, was started on June 11. The vertical shaft is now completed and timbered with square-sets of Oregon pine, to the 700-ft. point, and lateral work will be started on an elaborate scale when the raises are through. Lessees in the old incline are producing a fair tonnage of milling-grade ore.

Matt Edwards and E. G. Fink, of Victor, representing Eastern men, have secured a lease on the Ramona, on Bull Hill, and are figuring on a mill and mining machinery.

JOHANNESBURG, TRANSVAAL

DIAMOND-DRILLING ON THE FAR EAST RAND CONSIDERED UNRELIABLE.—SUGGESTIONS FOR BETTER METHODS.—A GREAT CENTRAL MILLING-PLANT SUGGESTED.

The news of the intersection of the reef by the bore-hole on the Spaarwater Farm, near the Nigel, on the Far East Rand, was received with much interest, and the assay results of the core were anticipated with some anxiety, by those interested in the property. The cores were described as apparently well mineralized but the assays have not confirmed the favorable first impressions. The top 4½ in. of the reef gave only traces of gold, the next 5 in. 2.4 dwt, the next 2½ in. 1.7 dwt, and the 4½ in. next the foot-wall only 2 dwt of gold to the ton of 2000 lb. Now, that the results have turned out so disappointing, the tendency is to place reliance only on the proved depth and

width of the reef, and none whatever on the assay values. Naturally bore-holes are only a limited guide to the true value of a lode, a fact which is generally recognized on the Rand. The Victoria bore-hole, near Germiston, put down to test the deep levels 25 years ago, yielding cores giving abnormally rich results, but subsequent mining operations have proved the neighboring ground to be the most poverty-stricken on the Rand. Nor were the excellent results of the Geduld bore-hole ever realized, while at Brakpan and Modder "B" the mining results have far outstripped those indicated by the bore-holes. Many similar instances might be quoted, but nevertheless, when the Spaarwater results are taken in conjunction with those obtained on the farm Vlakfontein belonging to the Lace Proprietary Mines, there is a tendency against regarding this portion of the Far East Rand as over-promising. The Spaarwater bore-hole may, after all, have struck a small patch of poor ground, or on the other hand, it may be a south-easterly continuation of the large low-grade area proved to exist near Boksburg, on which the Boksburg, East Rand Extension, Van Dyk, and Rand Collieries occur, and which to some extent would conform to the views expressed by Dr. Mellor on the Reef as characteristic of the Far East Rand. After all, the Spaarwater bore-hole has cast little further light on the mining value of this doubtful portion of the Far East Rand, and until shafts are sunk and the value of the reef proved by actual exposure, nothing reliable will be established.

Rand mining men have been somewhat severely lectured by George Denny, who says that during the last decade, he can see no pronounced changes or improvements in their methods, the tendency of Rand mining-methods being, he considers, to much along the lines of least resistance. These views, among others, were enunciated in a paper read by Mr. Denny before the South African Institute of Engineers with the object of providing matter for discussion at the subsequent meetings of the Institute. Mr. Denny pointed out that during the last dozen years while working-costs have apparently fallen 8s.4d. per ton, the yield during the same period has fallen 15s.9d. per ton, and he pertinently enquires, "how much of this reduced cost per ton is due to actually increased economy in working, and to what extent is it due to the milling of cheaply-mined ore, which may be returning less gold than it actually costs to mine and treat? Also to what extent if any is the marked reduction in yield per ton of ore milled due to the same cause? The reduced working-cost of ore milled on the Rand has been brought about by a variety of causes, principally cheaper fuel, railway rates, stores, explosives, adoption of electrical-power, more economical methods of development, and no doubt to a considerable extent, to the working of cheaply-mined ore, but not necessarily of unprofitable value. That the fall in the average grade of the ore milled to-day on the Rand, is not altogether or largely due to the milling of unprofitable ore, as suggested by Mr. Denny, is shown by the fact, that with scarcely a single exception, the value of the reef has declined with depth from one end of the Rand to the other. That the decline in value may be due to increased depth cannot be proved, but it is a coincidence not otherwise easy of explanation. Mr. Denny can no doubt remember a time when all ore below a value of 10 dwt. per ton was regarded as unprofitable, but to-day profits are claimed to be made on ore assaying less than one-half of that value. No doubt a large part of the profit earned today, is derived from ore, which during Mr. Denny's sojourn on the Rand, was considered too low in value to be mined and treated at a profit, but that to-day is capable of cheaper exploitation, and the whole aspect has changed.

Mr. Denny had much to say against each mine having its own milling equipment, on the score that it added to the capital expenditure unnecessarily. He even suggested one huge mill for 25 big mines on the Far East Rand. This is a new suggestion for the Rand, and in some cases might be followed with advantage, but big mills and concentration of milling

operations have not achieved the success anticipated on the Rand. An explanation of the uniform methods of treatment adopted on the Rand, even to becoming depressing, may be found in the uniform character of the ore, but it is scarcely correct to say that during the last decade no improved methods of treatment have been adopted here. Several instances may be quoted, however, where any radical departure from established methods have been attended with conspicuous failure.

There are, however, several statements in Mr. Denny's paper that are beyond dispute, and some of these suggestions are worthy of serious consideration. Many of these are not new, especially with regard to the want of a more rational method of expressing the value of ore-reserves, and what really constitutes profits and profitable ore, which, if I mistake not, were originally suggested by T. A. Rickard. The suggestion that other units rather than tons, should be adopted as a cost divisor, has also been made by H. Marriott. Undoubtedly the method of cost-keeping can be improved on the Rand, and in such a way as to assist the mine manager in keeping a more intelligent check on the profits, but it would scarcely result in bringing about such a revolution in Rand mining methods, as George Denny seems to consider imperative and necessary.

KOOTENAY, BRITISH COLUMBIA

NUMEROUS PROMISING MINES, THAT REQUIRE ONLY CAPITAL AND COMPETENT MANAGEMENT.—FAVORABLE WORKING CONDITIONS AND SHIPPING ORE.

The Steele group, in the North-East Kootenay district, adjoins the Lead Queen mine, and is a continuation of the Lead Queen vein. A 60-ft. cross-cut adit reaches the vein, but no drifts have been run, though the vein has been exposed on the surface for 300-ft., where it is 18 to 24 in. wide and assays from 35 to 50 oz. silver, and 50 to 60% lead per ton. The mine will be developed this summer and ore-shipments made.

The Delos group is on Boulder creek about three miles from the Horse-thief creek wagon-road. It is a Crown grant property and has been idle since 1898. It is reached by a good trail, which could easily be widened to a wagon-road. The ore is chalcopryite, with some gold and silver. This mine is situated on a zone of quartz stringers that intersect the slate in all directions—a stockwork 150 ft. wide. The quartz stringers are from one inch to two feet wide. An adit has been driven 53 ft. near the creek-level. It makes a good showing of copper ore. On the surface masses of copper sulphide are found in the quartz. It is the intention to mine and ship ore this summer. Clear ore runs 32% copper. There is considerable ore on the dumps ready for shipment.

The Bunyan group comprises four claims at the foot of Bunyan mountain, between Toby and Goldie creeks, and six miles from Invermere. The vein is 16 ft. wide, in which a pay-streak 3½ ft. wide runs 15 to 20% copper and 16 oz. silver. There is an adit in 60 ft., with some drifts and a winzo 20 ft. deep at one place, and numerous surface cuts, short adits and other superficial work. There is abundance of timber, and a good water-power is available. This property has been idle for several years. The Golden division is bounded on the south by the Windemere division, on the west by Ainsworth, Lardeau, and Revelstoke divisions; on the north by the Quesnel division, and on the east by the Alberta-British Columbia boundary.

The Monarch mine is 1000 ft. above the track of the Canadian Pacific railroad, three miles east of Field. The mine was discovered in 1885 and has since changed ownership many times. The camp-buildings and mill are at the railway, and are connected with the mine by aerial-tramway. The orebody is a replacement in limestone, and is from 15 to 30 ft. thick, with great longitudinal extent. The ore is sulphide, principally zinc. The mill is provided with the usual concentrating machinery, and has a capacity of 70 tons daily, turning out a

75 to 85% concentrate in which zinc runs 45 to 50% and the lead 55 to 65%. The mine has a good equipment of machinery, including a gas-engine situated at the top of the tramway and used to hoist supplies from the railroad to the mine. An adit has been driven 400 ft. on the orebody, and considerable stoping done on both sides. The mine is idle, though there seems to be no reason why it should not be in profitable operation with metals at their present high price. The property is owned by the Golden Giant Mines, Limited, of Victoria. The Giant mine is on the north side of the Spillimachene river, seven miles west of Spillimachene station. The ore occurs along the contact of limestone and slate, with an east-west strike and south dip of 60 to 80°. Barite is abundant in a zone 20 to 30 ft. wide, the limestone being silicified at a greater distance from the slate. In places the barite is impregnated with galena, from 5 to 10%, with a lower content of zinc, arsenic, and antimony sulphides. The galena is fine-grained and often is found in small seams. It carries silver to the extent of one ounce to each per cent of lead. An open-cut 60 ft. long, 50 ft. wide, and 30 ft. high at the face represents the main surface development. An adit has been run 325 ft., and 50 ft. below the open-cut another adit is in 265 ft., in which ore was first cut 60 ft. from the entrance. From the ore-bins just below the cut a gravity tramway has been built to the concentrating-mill. The ore goes to a Blake crusher, from which it passes to a Robins picking-belt conveyor. The ore drops onto a grizzly, the fine going to a fine-ore bin, the coarse being re-crushed and then joining the fine in the bin, from which it is fed automatically to rolls. The plant proved unadapted to the ore, and as a consequence the property has been idle for several years. In 1916 three cars of ore were shipped to the Trail smelter, and ran 26% lead and 5 oz. silver per ton. With proper machinery in the mill and competent management this property should be worked continuously and profitably. There are large outcrops of ore on the mine where practically no work has been done. Free water-power is available, and transportation facilities are good.

The Copper Butte mine is on a small branch of Bugaboo creek, five miles from Bugaboo creek wagon-road. This property was worked during 1916, though not steadily. Two cars of ore were shipped to Trail, which ran well in copper, which occurs as chalcopryite. Not having sufficient working-capital to operate the mine in an economical manner, the owner was forced to suspend operations. The Tennessee group is on Spruce Tree creek. The vein is from 3 to 10 ft. wide, with a streak 6 to 8 in. wide of solid chalcopryite, carrying \$3 to \$4 in gold and about the same value in silver per ton. The selected ore runs 23 to 33% copper, the entire vein averaging 13% copper. Work will be commenced early this summer, and the ore shipped to Trail.

Generally speaking, comparatively little work was done in the Golden mining division in 1916, but the increase in the price of metals has stimulated the owners of many mines to undertake active work during this season, and to ship their ore. What the district needs is more capital and experienced management.

There is a copper belt in the Selkirk range running north-westerly from Ditch creek to Fifteen-Mile creek. Orebodies are exposed in nearly every creek cutting through this belt, which is over 70 miles long.

Within a mile and a half of Canal Flat railroad station there are two parallel lodes on the north side of Findlay creek, locally called the East and the West lodes, respectively. These lodes are over 100 ft. wide in some places. The ridges rise from 300 to 500 ft. above the neighboring canyons; and mining facilities are unusually good. Timber and water-power are both abundant. The ores carry from \$1 to \$5 in gold, and from 1 to 40 oz. silver, and about 50% lead per ton. For large capital these lodes offer many promising opportunities, as mining and metallurgical operations can be carried on at low cost, and transportation facilities are better than in many

other districts where mining is successfully carried on.

Throughout the North-East Kootenay, including the Windermere and the Golden Divisions, there are many promising properties that require capital, and men who have had sufficient practical experience with mines of the type that are plentiful in this region. What is wanted here is men of the kind that developed the Slocan district, and who were not afraid to stay with the game through many disappointments and trials until they had made a success.

WILLOW CREEK, ALASKA

A QUARTZ MINING DISTRICT THAT IS MAKING GOOD.—PIONEER MILL METHODS GIVE PROFITABLE RESULTS.—A POWER COMPANY ORGANIZING.—DREDGING A SUCCESS.—A NEW PLACE DISTRICT REPORTED.

The Willow Creek District is approximately 75 miles from Anchorage, the headquarters of the Alaska Railroad Commission. Supplies reach this region either by way of the Susitna river or by way of the railroad to Wassili. The ore of this district is a free-milling, highly silicious ore, the high-grade ore usually occurring in shoots in the main ore-body. Coal may be obtained from the deposits of Matanuska, and a railroad-spur is run to within fifteen miles of the camps. Timber is scarce in the district, and is all brought in from other points near by. Good trails are being put in and there is automobile-service in the summer months.

No great depth has as yet been obtained on any of the ore-bodies, but in the history of this camp no vein has been known to have become impoverished or to have cut-out as depth was obtained. The mineralized region is approximately six miles square, containing innumerable veins. The ore has averaged for the year 1916 in the neighborhood of \$45 per ton, in many cases shipping-ore, running into the hundreds, is mined. A description of some of the larger plants will show how this camp is coming to the front while using milling-systems that to the modern mill-man seem like the arrastra, in comparison to up-to-date plants, yet making high recoveries.

The property of the Alaska Free Gold Mining Company, under lease to William Martin, of Seattle, is situated on Fishhook creek, one of the small tributaries of Willow creek. The ore occurs in several bodies, which are mined by a series of connected workings, no special line of mining being adopted owing to the nature of the veins, which are very irregular. Narrow stopes and workings of the Cripple-Creek type are most common in this high-grade district. The formation is diorite, striking N. 23° W. and dipping 30 to 35° south-west. Three aerial-trams connect the mine to the mill-bins, the mine workings being 1000 ft. above the mill. A 750-ft. tram on the east side of the mountain connects the mine-bins, of 100 ton capacity, with an intermediate station from which the ore is trammed by cars to a second bin 500 ft. away. From this second bin the ore is sent to the mill by means of a single-span, 2100-ft. tram. West of this tram two others, one of 2400, the other of 4500 ft. connect other workings with the mill, the buckets having a capacity of 500 lb. The ore on reaching the mill is crushed by a jaw-breaker to 1½ in. and fed to two 10-ft. slow-speed Lane mills. No screens are used, the size of the product being governed by the height of discharge and amount of water fed to the pulp. Inside amalgamation is practised with excellent results. The pulp after being discharged, is split and passed over 5 by 10-ft. plates set on a grade of 1½ in. to the foot. From these it reaches two Barnes concentrators; thence to classifiers, and then to the cyanide-plant. Concentrate is shipped to the smelter, the slime at present is being impounded for future treatment. The cyanide-plant consists of four tanks—two sumps and two for solution, each holding 30-tons. The pulp is treated for four days, the gold being precipitated on zinc-shavings, dried, and shipped. Power for the plant is furnished by a 10-in. turbine under 54-ft. head, and

two small gasoline-engines of 25 and 16 hp. that are hooked-up to the same line-shaft. The approximate length of season for this camp is six months, and while the mill is forced to close down during the winter, the development-work in the mine is carried on and ore blocked out for the coming season. This year work commenced on May 25.

Another producer is the Independence Gold Mining Co., whose claims are situated on the head of Fishhook creek. Two veins are mined on this property, one, the Granite Mountain, the other the Independence, both occurring in a formation similar to that of the Alaska Free Gold. On the Granite Mountain vein a drift of 265 ft. has been run. From the end of this drift an incline, flattening out about one-third the way down, has been sunk 480 ft. on the vein. Both overhand and underhand stopes have been opened from this, following the ore. Stulls support the roof, waste being used as pack-walls. Both veins strike N. 12° W. The dip of the Independence is 40°, the Granite Mountain dipping from 2° to 28° south-west. The Granite Mountain vein, up to the present, has been the most important one and that on which most of the mining and development work has been done. Two aerial-trams convey the ore to the mill. The ore passes over a 1-in. grizzly to bins, the oversize passing to a 7 by 9-in. Dodge breaker. From this it is automatically fed to a 3-stamp battery of 500-lb. stamps and one 1300-lb. Nissen stamp. Ore is crushed to pass 40-mesh, the pulp passing over plates set on a grade of 1½ in. to the foot. Inside amalgamation is practised. After passing over the plates the pulp goes to an Ogden concentrator, thence to the tailing-pond. The report is that the capacity of this plant will be increased by the addition of a 5-ft. 6-in. Denver mill. The pulp, after passing over plates, will go to Wilfley tables.

A property on which more work is to be done this season is owned by the Mabel Mining & Milling Co. Open-cuts and drifts have been driven on the ore. A Denver mill of 15-tons capacity will be operated again this year. An aerial-tram, 3500 ft. long, is used to convey the ore from workings to the mill.

George B. Dean, of Spokane, representing Spokane capitalists and Trust companies, will spend several weeks going over different Willow creek properties. He will leave from Anchorage in company with E. R. Davidson, of the Mohawk Mining Co., to examine that property with a view of installing a mill.

Wm. Martin has arrived at Anchorage and will leave there for the camp at the Alaska Free Gold Mining Co., of Willow Creek, on May 27. Mr. Martin has plans under way to establish a central power-plant to furnish power to the other operators in this region.

The Cache Creek Co.'s new dredge will commence work for the season in a few days. This ground was tested by James Murray for three years before the dredge was installed. A dredge of 15,000-cu. yd. capacity was installed and run for some time last year. The pay in this district is from 3 to 12 ft. from the surface. The property consists of 75 or more claims. No information is at hand as to the value per yard.

The report of a strike in the placer district near Nenana, known as the Brooks section, is current. Nothing definite regarding the value of the ground has as yet reached Anchorage.

KOWKASH DISTRICT, ONTARIO

A NEW GOLD DISTRICT IN NORTH ONTARIO THAT GIVES SIGNS OF PROMISE FOR THE NEAR FUTURE.

Interest in the Tashota section of the Kowkash gold area is increasing, and there is every indication that this summer will witness much activity there. It is over twenty months since gold was first discovered in the Kowkash district, and due to the fact that the camp was isolated from any mining town, being 300 miles from Porcupine, and about 400 miles from Cobalt, development did not proceed with vigor. However, the one property developed, by the Tash-Orne Mining Co.,

has stood up well under actual test. The main shaft is down 115 ft., and at the 100-ft. level driving both ways is going on. These drifts are now out over 100 ft. each way from the shaft and the vein, in which considerable free gold occurs, is the full width of the drifts. Also, the wall rock on either side of the vein carries gold for several feet back from the vein. This company also owns the King Dodds property, which it is preparing to explore. The small mining plant in operation at the Tash-Orne will perhaps be removed to the King Dodds and a larger plant installed at the Tash-Orne.

Two other properties being developed in a small way are the Hull-Kipper group, and the Wells claims. On the former, the owners, who are prospectors, remained on the ground during the past winter and sunk a shaft 50 ft. deep on a large zone of schist intersected with small quartz stringers. The stringers are rich in gold, but when averaged with the rest of the mass, the rock could scarcely be termed of commercial value. However, the property is likely to receive extensive development before long, with a view to finding, if possible, better ore at depth. Despite the fact that snow is still deep in the valleys and swamps, quite a number of prospectors are already on the Kowkash trails.

PLATTEVILLE, WISCONSIN

A NUMBER OF PROMISING NEW DISCOVERIES.—OLD MINES BEING RE-OPENED AND INCREASED PRODUCTION IS ANTICIPATED.

The Hazel Green district showed a slump in ore production, mainly through decreased shipments of ore from the Kennedy mine, one of the New Jersey Zinc Co.'s producers, which, however, recovered itself toward the last of the month. The McMillan Zinc Co., after two years of development got down to milling operations in the rebuilt Board of Trade mine equipment. Good strikes were reported in a score of borings on the lease held by the Rio Mining Co. The Cleveland Mining Co. made light deliveries most of the month from both of its producers, the Cleveland and Lawrence mines. From the Potosi camp came a car of high-grade concentrate each week from the Wilson mine. The Tiffany Zinc Co., with a new producer and a 500-ton mill was slow getting into action, but picked up toward the close of the month. Drillers were meeting with success on the Horse-Shoe lease where a new shaft was bottomed in zinc ore with a fair deposit of lead ore in the top openings. Several cars of lead ore came from that district during the month. The Galena district suffered set-backs in output, the Black-Jack mine, a New Jersey Zinc Co.'s producer, returning about one-half the usual output. The Graham and North Unity mines, Vinegar Hill properties, did well the second half of the month. J. H. Billingsley, president of the Frontier producers, and mayor of the city of Galena, purchased the Merry Widow mine that had been idle two years, and the plant was steamed up and dewatering of the workings began. Its operation now depends on a thorough inspection of the ore deposits which it is known were not entirely exhausted when the mine suspended production. It was proposed in the event this inspection should not meet expectations that a thorough drilling programme be inaugurated. Other mines will be taken over by the same interests when this property is again in operation.

KOREA

The following results for February has been received by mail from the Oriental Consolidated Mining Co.: 200 stamps, running time, 26½ days, crushing 23,885 tons.

Gross receipts for the month.....	\$132,443.20
Operating costs	82,683.71½

Operating profit for the month.....	\$49,759.48½
Put back into improvements and development work	2,929.12

Net profit over all expenditures for February....	\$46,830.36½
---	--------------

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

GILA COUNTY

With its full milling capacity in operation for a large part of the month and the high recovery from ores treated, a new production record was established in May by Inspiration Consolidated Copper Co. at 11,900,000 lb. of copper. Although constituting the highest monthly yield to date, the May total was but slightly in excess of that of September 1916 output of 11,850,000 lb. when there were but 18 available mill sections. At that time, however, the grade of ore treated was higher than of late. During May, the average grade of ore at times ran below 1% copper, but the mill operations were so efficient and the tonnage milled so large that it more than offset the conditions in September. The management is figuring upon a monthly copper production exceeding 12,000,000 pounds.

YAVAPAI COUNTY

The Arizona Central Mining Co., of Houston, Texas, has taken an option on two groups of claims, at Copper Basin, that are owned by Fred Williams, Joseph Hobbs, and others, of Prescott. There are several shafts on the property, sunk on veins 3 to 10 ft. wide carrying gold, silver, lead, copper, and zinc. The property is near that of the Commercial company, one of the Phelps, Dodge subsidiary companies.

YUMA COUNTY

(Special Correspondence.)—One of the most promising new mining districts, is the region tributary to the Arizona and California railroad, from Wickenburg to Parker, a distance over 100 miles. One of the most active of the small towns is Wenden, the outfitting point for Cunningham Pass, 12 miles north. The Cunningham Pass mines have come into prominence only within the last year. The last few months two properties have been developed, the Black Giant and the Wenden King. Both properties have installed machinery and started to sink. The Black Giant is said to be completely financed to sink to the sulphide zone. A camp has been built, a hoist installed, and a compressor is said to be on the way. The Wenden King has just finished installing a hoist and compressor. Another company, the Wenden Verde, has recently entered the Pass district and it is reported it has ordered machinery, which is expected to arrive in a few days. The property which has shipped the most ore from this district is the Critic. The last car netted the leasers over \$100 per ton. The Black Reef Copper Co. also has installed a new plant with a capacity to sink over 500 ft. A compressor also has been put in. It is the intention to do deep mining.—The Wenden Copper, is another property, which started development work in the last year, with 20 men working continuously. Originally all of these properties were owned by prospectors who chlorided the surface ores of unusually high-grade in copper and gold, and while not a great amount of ore has been shipped, there has been more ore shipped for the amount of development work done than from any other district in this part of Arizona.—Other properties are the Bullard, the Desert Mining and Development Co., and the Rainer. The Bullard property has been leased and bounded to Mr. Donnelly, who recently had charge of the Wenden King. Mr. Donnelly was formerly with the Goldfield Consolidated. The Bullard has shipped 28 cars of high-grade from surface adits. The Desert, which has been closed down temporarily, is going to resume operations soon. The workings are not down to water-

level yet. It is said that there is over 40 ft. of low-grade copper ore in this mine. Considerable money has been spent in opening up this property, and some think that this expenditure more than justified the expectations.—The Rainer company has planned to drill its property either by churn or diamond drills.

Wenden, June 14.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—It is reported that some Kansas promoters are engaged in sampling the Tierakoff mine with a view of early re-operating. The Tierakoff is an extension of the Sawyer claims. It was worked many years ago. The mine is across the Mokelumne river, from the Lone Star mine in Calaveras county.—The Newman mine is steadily producing and everything is said to be satisfactory to the owner.

West Point, June 15.

CALAVERAS COUNTY

(Special Correspondence.)—The Buffalo Gravel mine in Chile gulch, about a mile from Mokelumne Hill, is erecting suitable buildings for accommodating the men at the mine. They are installing a 10-hp. Dow electric pump, which recently arrived. This looks promising and will, no doubt, encourage others in the near future to follow this enterprising example. The Safe Deposit gravel mine, also in Chile gulch, has had an entire change of staff, Wm. Burgess having sold his interest in the mine. An expert pipeman to lay all the necessary pipe, arrived from San Francisco recently.—Major Rand, of the United States Engineers, was up on business connected with the water and debris-dams of placer-miners.—The Corral Flat gravel mine, formerly known as the McKee and McGaw, near Mokelumne Hill, will start with a full force in the near future. The directing engineer is at present in the East. Driving to catch the channel is in progress.—The cross-cut adit of the Hector drift-mine is now in 3800 ft. Mr. Chapman, the superintendent, who was for over a year at the Greenwater, in Death Valley, had an automobile accident at Tracy, when the steering-apparatus broke.—The Lucas quartz mine, situated near the Mokelumne river, and consisting of five claims, is uncovering rich ore, some of it going as high as \$500 per ton. An average of \$50 per ton is obtained. The mine has produced considerable in the past, but the former owners missed the rich shoots. Robert Irvine, of Mokelumne Hill, owns three of the claims. The Mokelumne Hill group is running the mill, two shifts, on ore from the west-adit stopes; the ore is sulphide in diorite. The east and west veins carry the value.—The Boston, or the Esperanza, owned by Sam Davidson, of Mokelumne Hill, is awaiting the arrival of a Mr. Baker from San Francisco.—The Maypole quartz mine is practically at the end of the caved ground. Much re-timbering had to be done to catch it up, but it was finally accomplished. Leonard G. Blakeman, of Stockton, is superintendent.

Mokelumne Hill, June 12.

(Special Correspondence.)—P. B. R. Lightner, of Stockton, is steadily sinking on the La Petite quartz mine near this place. The ore that was struck at the 100-ft. level is holding up in value.

Railroad Flat, June 15.

SIERRA COUNTY

H. L. Johnson has received the final payment on account of

the transfer of the Tightner mine, and it is reported that the present owners also distributed a dividend in May among those interested.

The Bernhardt Bros. are credited with having washed nearly 107 oz. of gold from 600 cars of gravel at their Hilo mine. This is at the rate of over \$3 per car. There remained about 400 cars more in the block of ground from which the clean-up was made—a pillar left in the working by old-time miners, but the ground caved, cutting them off from the pillar, and a drift had to be run around the caved ground to get into new territory.

John Addison was injured recently at the Brandy City hydraulic mine in a peculiar way. He was in charge of one of the monitors, and was directing the stream against the gravel when lightning struck the pipe-line, followed the pipe to the monitor, and knocked the miner down. After recovering somewhat from the shock he started to walk to the blacksmith-shop, when another and heavier flash struck the bank and brought down several hundred tons of volcanic cement overlying the channel-gravel. Addison was hit by a large boulder rolling down from the shattered mass of rock, and injured more seriously than before. In addition to these injuries he was nearly drowned by a flood of water from a 22-in. water-pipe that was broken by the fall of the cement. He is back at his post again, having fully recovered from the several injuries of his eventful day.

SISKIYOU COUNTY

(Special Correspondence.)—M. A. Delano, of Grants Pass, Oregon, who owns the Bon-Ton group of four copper claims on Ike's gulch, or Slater creek, and who bonded the Mohawk and Copper King, has commenced development on these two properties.

David Land and C. J. Tuey, of San Francisco, who have been prospecting the Williams Brothers' placer diggings along the Klamath river, at Wingate creek, have completed their work.

Joseph Kinash, hydrographic engineer, of the United States Geological Survey, is taking measurements of discharge in Klamath river and Indian creek, also in the Reeves Davis Consolidated Mines Co.'s flume.

Harry Morrison and James G. Gallagher, of Philadelphia, Pennsylvania, are among mining men to arrive lately in this camp.

Alvin Smith and T. C. Ince are building a bridge across Slater creek in Wood gulch, to be used for hauling logs to their mill, and supplies to the mines in the Ike's Gulch district.

Mr. Kernor, superintendent of the Grey Eagle mine, is moving the office effects of the mine to new quarters on Indian creek adjacent to the mine. Two diamond-drills have been constantly developing the orebodies of the Grey Eagle mine for the past three months.

Earnest Helliare, of Grants Pass, and New York, is expected to arrive in Happy Camp to develop several copper properties in this district.

Local people are developing a number of promising copper claims of the Commodore group near the headwaters of Barkhouse creek, a tributary of the Klamath river.

Prospecting is active throughout this district. There are many prospectors in the hills, also prospective buyers of promising claims. Among the recent arrivals at the camp are Jesse Gorden, of Bakersfield, California; J. E. Perry, of Riddle, Oregon; Henry Phillips, of Oakland; George Thompson, of Reno, Nevada; M. White, of San Francisco; and Harry Wayland, of Ogonze, Pennsylvania.

Henry Doolittle, a merchant of Seattle, has arrived in Happy Camp, and will take up his residence here for a short time to adjust the affairs of the Doolittle estate, of which he is the administrator. The estate owns the Camp site, and adjacent lands. He will have the property laid out into town-lots, pro-

viding for commodious thoroughfares and parks essential for the needs of a modern city. This meets the wishes of the residents of the little town.

John F. McCoy has a large force of men employed in making trails up Slater Creek gulch, and the Dakin ridge to Slater gulch. An early survey will be made of this property and a camp built. The property lies to the east of the Grey Eagle mines and adjoins that property.

Happy Camp, June 15.

COLORADO

BOULDER COUNTY

(Special Correspondence.)—The Dupont-Wooding company, at Denver, has taken the Huron mine under lease and option and will begin systematic development. The General Lee mine, an adjacent property, owned by Mrs. S. A. Martin, it is reported has passed into other hands, and will be worked. This property has a fine body of ore exposed in the face of the adit. Otto Victor and associates have a splendid showing of silver-lead ore in their property on Tennessee mountain. When the Consolidated Leasing Co., of Columbus, Ohio, of which C. E. Kahler is president and general manager, gets its mill built, the mining industry at Eldora will be given an impetus which will result in many good old properties that are now idle, being opened up, and steadily worked, thanks to custom-mill, as high cost of freight heretofore has prevented many properties from shipping. The Good Friday mine, at Boulder Falls, which has been a steady producer of tungsten ores the past year, is getting ready to work one of the largest blocks of ore in the county. The management has now developed the mine to a stage where the natural disadvantages of the situation will be overcome and a constant production of ore will be made. N. H. Brown is general manager, and C. W. Roche is foreman. The Good Friday vein, which is a part of the lower vein that runs through the Eureka, Luckie 2, and April Fool properties, has differed from most tungsten deposits in that it has produced pockets; but the vein has been practically continuous throughout the entire development of all of these mines. This property is one of the claims of the Mojave-Boulder Tungsten Co., a New York concern. J. N. Baer has a lease on the April Fool mine, one of the properties in this group. Brown and Lewis have begun unwatering their mine at Loveland and intend starting development. The Red Sign Company, in Millionaire gulch, is resuming operations on its properties. The Logan mine has been taken over by the Lucky Dick Mining Co. The new company will do a large amount of development work. The Eureka mine has been leased to operators who will begin work promptly.

Eldora, June 13.

IDAHO

SHOSHONE COUNTY

The Success Mining Co. will resume dividends at an early date is the announcement authorized by P. J. Gearon, the manager. The large orebody that has been developed on the 1400 and 1500-ft. levels has placed the property in fine position for production, and shipments are being made at the rate of 2000 tons per month. The shaft has been sunk to the 1600-ft. level and a skip-pocket cut. Cross-cutting to the ore will begin which is expected to be reached by the middle of June.

According to the statement of F. W. Bradley, president of the Bunker Hill & Sullivan company, it is the intention of the company to begin the construction of an electrolytic zinc-refinery as soon as the new smelter is in operation, says the *Wallace Miner*. The Bunker Hill & Sullivan is not a producer of zinc ores, but there is an abundance of zinc ore in the district, and a refinery such as is now proposed would afford a local market for ores of this kind. The elimination of the cost of transportation for ore to outside zinc plants would be welcomed and would make it possible for some mines in which

zinc occurs, which are now struggling for an existence or idle, to work at a profit.

The initial capacity of the new plant will be 300 tons per day. It is to be situated near the smelter and will be planned with a view to enlargement.

MICHIGAN

HOUGHTON COUNTY

Every man that can be spared from actual production work is being used by the Lake Superior copper mines on the biggest construction program ever undertaken. The mine managers are putting many thousands of dollars into work which will lower production costs in the future, says the Boston News Bureau.

The Mohawk, Wolverine, Quincy, and Calumet & Hecla have started work on fire-sprinkler systems in their mills. Mass Consolidated is increasing its mill capacity, the Mohawk-Wolverine mills are installing an expensive new turbine and new launders; a turbine is going in at the Ahmeek mine; Calumet & Hecla is adding a new 12,000-kw. turbine to operate the new electrical tramming and mining-devices recently installed. Isle Royale, Adventure, Mass, Lake, Ahmeek, Keweenaw Copper, and Osceola are building new houses for employees, and many mines are adding new shops, and the Tamarack mill is being enlarged.

The Chilean mills at the Calumet & Hecla re-grinding-plant No. 1 are being replaced with Hardinge conical-mills. The Calumet & Hecla is planning to build a big flotation-plant and is increasing the capacity of its leaching-plant from 2000 to 4000 tons daily. The Calumet & Hecla is spending thousands of dollars on its Torch Lake plant to recover a higher percentage of copper and to treat its great pile of tailing. Many mines are also spending money on mechanical-haulage and working out intensive mining systems whereby more rock can be mined and hoisted per man employed than was customary under old systems.

MONTANA

LEWIS AND CLARK COUNTY

(Special Correspondence.)—At the property of the Marysville Gold Mining & Development Co. work has been in progress since last fall, the result of which is a large tonnage in sight, and it appears only a question of time when works will be built to treat the ore of this mine. The value is still all in gold and much of the ore blocked out is free-milling, some of it being high-grade.

Marysville, May 22.

SILVER BOW COUNTY

(Special Correspondence.)—The North Butte output for the month of April was 1,911,763 lb. of copper, 94,769 oz. of silver, and 123 oz. of gold. This is a big falling off from the March production and was caused by the fire at the Modoc mine of the Anaconda company.

The Speculator shaft is being re-timbered and will be ready for use about the first of June. When this has been done it is expected to bring the production of the Granite Mountain and Speculator mines up to 3,000,000 lb. of copper per month.

At the Bonanza mine of the Anaconda company record time is being made in shaft-sinking. Only three men are working in the bottom and these men have sunk 490 ft. since January 2. Butte, May 22.

GRANITE COUNTY

(Special Correspondence.)—Butte men have taken over the Swastika mine. It is planned to sink to the 500-ft. level and cross-cut the property from that point. The company is installing new machinery and in the meantime will continue to ship from the orebodies that are opened up. The Granite-Bi-Metallic property is working 200 men, and the manganese mines are booming; several companies are at work taking out manganese ore on which there is a big profit. The agents of

Eastern concerns are paying as much as \$10 per ton for the ore at the mines.

Phillipsburg, May 22.

NEVADA

EUREKA COUNTY

(Special Correspondence.)—Ore has been found on the lower levels in the California mine, by J. Robealati, the manager, who has been running a cross-cut to open up the orebody which was known to exist at depth. A 4-ft. vein of 56 oz. silver ore has been opened up in the Mt. Hope district by Ben Repetto, and associates.

Eureka, June 14.

ESMERALDA COUNTY

The production of the Goldfield Consolidated mines during April was 27,000 tons of ore, from which a net profit of \$15,007.32 was realized. During that month development was done to the extent of 1501 ft. at a cost of \$5.66 per foot.

The operating costs were as follows:

	Ore handled, per ton	Total ore, per ton
Mining:		
Stoping	2.381
Development	18.828
Total mining	2.710	\$2.262
Leasing expense	2.688	0.057
Dump moving	0.407	0.056
Transportation	0.067	0.067
Milling	2.022	0.016
General expense	0.287	0.287
Bullion tax	0.013	0.013
Filter royalty	0.025	0.025
Flotation royalty	0.146	0.072
Surface	0.054	0.054
Total operating costs		\$4.931
Miscellaneous earnings		0.062
Net operating costs		\$4.869
Construction
Net costs		\$4.869

DEVELOPMENT OF MAIN LEVELS

Mohawk: On an intermediate, above the 350-ft. level, 202EXY sill was extended and produced 34 tons of \$13.02 ore. On the 350-ft. level, 380 ft. north from the shaft, 215SZ sill was extended and produced, 63 tons of \$11.92 ore.

Laguna: On the 600-ft. level, 650 ft. south-east from the shaft, 450-M winze was sunk and produced, 127 tons of \$47.75 ore. There was no development of ore of any importance in any of the other mines.

Lessees: During the month lessees produced 576 tons having a gross value of \$8571.49, of which the company received \$5436.78, less the cost of transportation and milling.

HUMBOLDT COUNTY

The De Soto group of mines, 10 miles south of Mill City, is to be re-opened, according to the Lovelock Miner. The company will be known as the De Soto Consolidated. A great deal of rich ore was mined at the De Soto, Sheba, and other mines of that vicinity in the early days, the high-grade being hauled by teams over the Sierra Nevada mountains to Sacramento, and then shipped by boat or railroad. The value was chiefly in silver, and some of the ore was worth over \$1000 per ton.

WHITE PINE COUNTY

(Special Correspondence.)—Chas. Ruden has sold the old Maryland mine which he has owned and worked for the past 10 years to Robert Kelley, one of the owners of the California mine near Eureka. The new owner has bought a Blake crusher and will put in a jig and work the old dumps. He will

also put in a small hoist and a pumping-engine to furnish water for concentrating. The Maryland has been a producer for many years. The first ore taken out was shipped to Swansea, Wales, for treatment.

Eureka, June 12.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—Metal production by Mogollon Mines Co. for first half of May was 14 bars gold-silver bullion, in addition to which three tons of high-grade concentrate was shipped to the smelter.

Re-timbering of the Deep Down shaft by The Oaks company is rapidly proceeding and it is the intention to install an electric pump, as the work will shortly be down to water-level. At the Maud S. mine the continued opening of good mill-ore in new places is meeting the expectations of the company. All available burro-trains are being employed in daily shipments to the custom-mill.

The construction of a tailing-flume by the Mogollon Mines Co. has reached a point below the Maud S. property, where the canyon is narrow, with perpendicular walls, and the flume is being suspended by cables, anchored to either side of the cliff.

Auto-trucks are being utilized in macadamizing the grade over the mountain. Where the road has been finished it gives promise of permanency in all kinds of weather.

Mogollon, May 31.

(Special Correspondence.)—The Socorro Mines Co. cleaned up 1800 lb. of bullion for the last half of May, making nearly two tons of gold-silver for the month. Work has been about completed on the main Silver City road over the mountain. A good covering of crushed rock has been used, this being brought from the mines by trucks. The Oaks Company continued to increase operations during the week. More burros have been secured for Maud S. ore-shipments and ore is steadily being shipped to custom-mill. New ground is being opened up which is proving satisfactory to the operators, the grade being well above the camp-average. Work on the tailing-flume is being pushed as fast as lumber can be had. Development work on the Trilby group is being carried on by the owners. Good ore has been opened and is being developed.

Mogollon, June 15.

OREGON

BAKER COUNTY

A rich strike in the Irondyke mine at Homestead is announced. According to the common report a body of copper-gold ore has been cross-cut 125 ft., the ore of which assays 5% copper, \$12 in gold, and 2 oz. silver per ton. After a long idleness the Irondyke mine was re-opened in 1915, since which time it has shipped to smelters over 30 cars of ore monthly, from the proceeds of the sale of which the company has paid off the purchase price of the property, \$600,000. The principal development is a 3-compartment shaft sunk from what is known as the west adit-level. The newly discovered orebody is 850 ft. from the surface. It is supposed that the ore will extend both upward and below the level at which it has been exposed. No driving has yet been done so the length of the shoot is unknown. The property is under lease and option to the Irondyke Copper Co., of Pennsylvania, of which F. F. Curtze is president, F. A. Breveller is secretary, and A. A. Claus is treasurer, all of Erie, Pennsylvania. Emmett Gilligan is superintendent.

JACKSON COUNTY

(Special Correspondence.)—Asbestos in limited quantities has been uncovered at times and at various points in this region, but it has been of too short fibre to prove of commercial value. Recently, however, a deposit of long-fibre asbestos has been located in the Shelly Creek mining district, below Grants Pass. The extent of the discovery has not been demonstrated. The best developed asbestos property in Gold Hill

district is situated on the south slope of Cedar mountain, on the Umpqua divide at the headwaters of the West Fork of Evans creek, 20 miles north of Gold Hill. It was developed by George Houck, and Irvin Ray, of Gold Hill, 10 years ago. The vein is 4 ft. wide. It is at an elevation of 4000 ft. The fibre runs from 10 to 16 in. long and is of fair commercial value. It is 12 miles to the terminal of the wagon-road leading to this valley, which is the only outlet. Recently there have been many inquiries in this district regarding asbestos.

Another auto-truck was added this week to those hauling copper ore from the Blue Ledge mine to Medford, making 14 to arrive from California, all of which are in service. The road is in bad condition, making the transportation of ore slow and expensive. Improvements are contemplated by the county, assisted by the mine and truck owners.

In Douglas county, near the Jackson county-line, a few miles from Tiller postoffice, a promising vein of cinnabar is being uncovered on the Webb-Hayes property. This prospect seems to be an extension of the large dike carrying cinnabar, which runs through the Ramsey canyon and Meadows districts, north of Gold Hill.

Those who have visited this district of late have found that the chrome deposits, especially those in the Waldo district, are of sufficient importance to justify development. It is assumed that for a number of years the deposits in this region will be a source of profit and a field for numerous laborers.

Reorganization and refinancing of the Rogue River Public Service Corporation, of Gold Hill, was forecast last week when, upon the petition of Francis M. Fauvre, vice-president of the company, Federal Judge Wolverton, at Portland, appointed J. F. Reddy and George M. Soranson, of Grants Pass, joint receivers. The Rogue River Public Service Corporation owns important water-power rights in southern Oregon on Rogue river, including the huge Ament dam, situated between Gold Hill and Grants Pass, and a completed wing-dam power development project at Gold Hill. The reorganization is of much local interest, as the company has been of vital importance to the mining industry in this district in the past. The company operates the municipal water-plant of Gold Hill under lease.

Gold Hill, June 14.

SOUTH CAROLINA

ABBEVILLE COUNTY

The Sullivan Mining Co is operating a 50-acre tract three miles from McCormick. The main shaft is down 110 ft., and in a cross-cut at the 60-ft. level 18 veins from 6 to 24 in. wide are said to have been cut. At 100 ft. a vein 4 ft. wide carries ore worth \$10 per ton. A drift has exposed this vein for 20 ft. Ore of 20-oz. grade is reported from some of the smaller veins. The shaft has two compartments, with hoist and pump-way.

Ore is hoisted in a bucket and fed to a gyratory breaker, falling into the mill-bin, thence through automatic feeders to two 5-stamp batteries. Inside amalgamation is practised and a successful method for saving so-called greasy gold. Quick-silvered copper plates are used and the tailing runs to waste. The installation of two concentrating-tables is contemplated in the near future. A 45-hp. boiler furnishes steam for mine-pump and hoisting-engine. The whole plant is built in a miner-like way, and under the conditions seems to be an economical one.

TEXAS

LLANO COUNTY

(Special Correspondence.)—W. B. Phillips, of the Bureau of Economic Geology and Technology of the University of Texas, in discussing the possibility of platinum ores being found in that State, says that a few years ago a company, while engaged in gold mining in Llano county, made a number of assays of a material found on the property which was thought to contain platinum. The results showed that a maximum of 0.42

oz. and an average of 0.24 oz. of platinum per ton of rock was contained in the ore. The platinum is associated with a little gold and bismuth, possibly as telluride of gold and telluride of bismuth, and to exist as the arsenide of platinum, known as sperrylite. The experimental work resulted in the production of an alloy of platinum and lead, the content of platinum being about 70% of the alloy. So far as known this is the only important occurrence of platinum in Texas. Much still remains to be done before anyone can venture to express an opinion, at the same time the occurrence of platinum in this State is interesting. In Llano county the platinum occurs in quartzite closely associated with the graphite-bearing schists at the Heath gold mine, five miles east of Llano. Platinum also occurs there in granite and hornblende schist overlying the granite. The old shaft is in bad condition. On the same property there is an extensive deposit of flake graphite, together with molybdenite and molybdeite.

Llano, May 27.

REEVES COUNTY

(Special Correspondence.)—The development of the sulphur deposits of western Texas are beginning to assume increasing importance. The recent incorporation of the United States Sulphur Co., with a capital stock of \$600,000, and general offices at Dallas, is taken to mean that there will be a large increase in the output of refined sulphur from this region as soon as the company can install the necessary machinery and equipment. It will build a large sulphur refinery, and besides removing the impurities from the crude material it will manufacture sulphuric acid. The men who compose this company have been carrying on exploration work on their sulphur deposit for several months and have uncovered upon a tract of 40 acres sulphur amounting to more than 2,000,000 tons. At present prices, even for the crude ore this mineral in sight is worth a large amount. The sulphur outcrops in many places over a large area of country besides that which has already been partly explored.

Toyah, June 4.

CANADA

COBALT, ONTARIO

(Special Correspondence.)—The Nipissing Mines Co. has declared its regular dividend of 5% payable July 20 to shareholders of record June 30. This means the disbursement of \$300,000, and brings the total paid so far during 1917 up to \$900,000, and a total since the initial disbursement, of \$16,246,000. This is equal to 264% on the company's issued capital.

Cobalt, June 11.

MEXICO

(Special Correspondence.)—The revival of mining operations in the Cananea and Nacozari districts of Sonora, is shown by the custom-house figures of the exports to the United States during the month of May of ore, concentrate, and bullion. From the Cananea district there were sent into the United States during May 5,407,600 lb. of copper and 16 cars of copper, zinc, gold, and silver ores, having a total value of \$4,163,400 gold. From the Nacozari district the concentrate for the month had a value of \$2,019,700 gold. It is expected that the exports from those districts for June will be larger than in May. There promises to be also heavy shipments of concentrate and bullion made from other districts in Mexico where the operation of mines and mills has been resumed recently. They will come principally from the Monterrey region with the possibility that some of the districts in the states of San Luis Potosi and Zacatecas will also become shippers.

Cananea, June 12.

WASHINGTON

The Boston American Mining Co. is planning a 200-ton mill for the Monte Cristo mine, at Monte Cristo. H. deS. Kennedy will have charge of the construction.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

J. PARKE CHANNING has returned to New York.

A. M. BATEMAN has gone to Kennecott, Alaska.

H. P. GORDON has returned from Chichagoff, Alaska.

J. D. IRVING was in the Coeur d'Alene region recently.

J. M. BOUTWELL and E. S. BASTEN are in South America.

F. W. BRADLEY was at Portland, Oregon, during the week.

L. D. RICKETTS is recovering from the effects of his recent illness.

ERNEST R. WOAKES has returned to London from the Argentine.

R. S. BAVERSTOCK has returned to Los Angeles from a trip to Lida, Nevada.

ROSS B. HOFFMANN is examining dredging conditions in the Yuba goldfield, California.

D'ARCY WEATHERBE is due here from Toronto. He will sail on the 'Tenyo Maru' on June 29.

W. W. MEIN has arrived here from New York, expecting to spend the summer at Lake Tahoe.

ROBERT C. STICHT will address the San Francisco section of the A. I. M. E. on July 10, on 'Pyritic Smelting.'

PAUL W. AVERY is here from El Oro, Mexico, on a short visit.

C. E. GRUNSKY, JR., has resigned the secretaryship of the local section of the A. I. M. E. owing to his military duties.

R. H. STEWART, formerly manager for the Consolidated Mining & Smelting Co., at Trail, B. C., has opened an office as consulting engineer at Vancouver.

VALERIUS, McNUTT & HUGHES have opened an office in the Fayette National Bank building, at Lexington, Kentucky. They will specialize in petroleum geology.

H. N. STRONCK has been appointed vice-president and managing engineer of the Illinois Engineer, Auditing, and Public Relations Co., 122 S. Michigan avenue, Chicago, this firm being successors to Benedict, Boyle & Stronck.

HENRY S. MUNROE, emeritus Professor of Mining in Columbia University, has been awarded the medal given by the class of 1889 for the most distinguished piece of work done by a graduate of the Schools of Mines, Engineering, and Chemistry.

Obituary

ALFRED HOFFMAN PINTHER died May 22. He was the senior member and president of the firm of Hoffman Pinther & Bosworth, of Mexico City.

EUGENE H. T. CHEN, a graduate of the mining college of the University of California, came to his death in the Province of Yunnan, China, recently, as a result of a forest-fire, thought to have been started by brigands. Mr. Chen, upon graduating from the University, returned to his native land and engaged in his profession in Yunnan. He is described by his friends as a man of marked ability, and his death will be greatly regretted by all who know him in California.

On April 17, WILLIAM SWANCOTE, the pioneer of zinc mining at Hanover, New Mexico, died at his home in Hanover. A week previous to his death he received a severe fall; later pneumonia set in, from which death resulted. Mr. Swancote was born in Wales, in 1844; and came to Central City, Colorado, in the early 70's. and in 1884 went to New Mexico for the Mineral Point Zinc Co., for which company, and its successor, the Empire Zinc Co., he was superintendent of mines until 1915. Mr. Swancote represented the highest type of manhood; he was an honor to his company and to the mining industry. All who knew him called him friend, and his passing will be mourned by the great company in which he was so many years an important factor.

THE METAL MARKET

METAL PRICES

San Francisco, June 19

Antimony, cents per pound.....	19.50—22.00
Electrolytic copper, cents per pound.....	34.50
Pig lead, cents per pound.....	12.25—12.50
Platinum, soft and hard metal, per ounce.....	\$105—111
Quicksilver, per flask of 75 lb.	\$82
Spelter, cents per pound.....	11.50
Tin, cents per pound.....	59
Zinc-dust, cents per pound.....	20

ORE PRICES

San Francisco, June 19

Antimony, 50% metal, per unit.....	\$1.35
Chrome, 40% and over, f.o.b. cars California, cents per unit.....	50—55
Magnetite, crude, per ton.....	\$8.00—12.00
Tin, cents per pound.....	60
Tungsten, 60% WO ₃ , per unit.....	20.00
Molybdenite, per unit for MoS ₂ contained.....	40.00
Manganese, 45% (under 35% metal not desired), cents, unit.....	36—38

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 49% metallic manganese.....	Per unit \$1.00
46 to 49% metallic manganese.....	0.98
43 to 46% metallic manganese.....	0.95
40 to 43% metallic manganese.....	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

EASTERN METAL MARKET

(By wire from New York)

June 19.—Copper is easier but dull at 32.75 to 32.50c. Lead was quiet and strong all the week at 12c. Zinc is quoted at 9.75 to 9.67c. Platinum remains unchanged at \$105 for soft and \$111 for hard.

Samuel Montagu & Co. in their weekly letter, dated London, May 24, say of silver: The tone of the market continues to be remarkably steady and the price has moved again within very narrow limits.

Since May 2nd last, the quotation has never been more than 1/4d. either side of 38d. From May 10th on, it has been either at 37 1/2d. or 38d.

There has been an absence of business from the East; buying orders have been mainly for coinage as usual.

There has been a considerable drop in the Indian price. It fell in Bombay from 103% to 100%, duty paid, following the collapse of a local corner for delivery. The fact that the price has been moving above 100 rupees per 100 tolas is suggestive, and throws a light upon the bearish attitude of the Indian Bazaars, which has obtained for some time past, and also upon the way in which the Indian people have been content with such reduced imports for industrial consumption.

It is more than probable that many individuals whose silver jewelry depreciated seriously when the Indian mints were closed to free coinage, have taken advantage of the high prices, compared with those ruling for the last 20 years or so, and have turned their silver bangles into silver coin. This action would account for a proportion, though probably slight, of the excessive drain demand for silver rupees during the last two years.

The figures relating to the Indian currency show a large increase in the note issue, and for the first time since March 31 last an increase in the silver holding by the Treasury.

The stock in Bombay consists of 2000 bars, as compared with 2200 bars last week.

The stock in Shanghai on May 19 consisted of about 26,600,000 oz. in sycee and \$17,500,000, as compared with about 29,000,000 oz. in sycee and \$17,700,000 on April 12.

COPPER

Prices of electrolytic in New York, in cents per pound.

Arrangements are being made to simplify the distribution and control of tin, and these arrangements are expected to get the trade all the tin required. The prices have therefore shown a considerably easier tendency and the market is nominally quoted at 60 1/4c. for spot delivery, with Banca and Chinese tin at a great discount. Banca has actually been done at 55 cents.

TUNGSTEN

The tungsten market is extremely firm, with very little offered, and at the present moment there is more demand than supplies, especially for scheelite, which is practically sold out for early delivery. The market has been quite firm at schedule prices, with continuous inquiries for home and foreign consumption.

MOLYBDENITE

Molybdenite remains unchanged and firm at \$2.20 per pound MoS₂.

ANTIMONY

Antimony has been exceedingly active during the past week, though at prices gradually declining, and spot antimony is quoted at 20 to 20 1/2c.; August shipment, 15 to 15 1/2c. Needle antimony is firm at 12c. for spot, with futures quoted at 9 1/2c., which is a higher figure than before on account of the freight rates from China being continuously on the increase. Antimony ore remains unchanged with buyers at \$2.30 per unit.

MANGANESE

The manganese market continues firm and \$1 a unit was actually paid for high-grade ore f.o.b. New York. Chemical ore prices are unchanged.

Eastern Metal Market

New York, June 13.

All the metals are much less active than for some weeks, and are generally held in restraint by uncertainties due to the attitude of the Government and to other conditions.

Copper is quiet but firmer, especially for future deliveries.

Zinc is dead but firm.

Lead is higher but not active.

Tin is dull but steady and firm.

Antimony continues to decline in an inactive market.

In the iron and steel market pig-iron continues to rise and advances are recorded over the remarkable ones reported a week ago. Bessemer iron has sold for \$55 per ton on small sales and basic iron has touched the \$50 mark, an advance of \$5 on sales of more than 50,000 tons. Melting steel scrap has sold at \$42.50 at Pittsburg, an advance of \$12.50 in two weeks. Rapid strides have been made in the ship-building program in the past week, and the project for a yard in the New York district, for which large steel interests will carry on fabrication on an unheard of scale, is rapidly taking shape under the lead of the Submarine Boat Co. Shell contracts for the Government total 9,000,000, requiring 80,000 tons of steel. On domestic ship-plate inquiry 11c. and higher has been quoted, and France is asking for 25,000 tons of plates and shapes for ship repair-work. The demand for both black and blue annealed sheets from automobile plants and other sources has reached large proportions. The entire steel trade is much at sea as to the future steel-supply for general consumption, and the lengths to which prices will go.

COPPER

Despite the fact that sales are in small volume for any position, and that demand is not large, the market grows firmer every day. In general, quietness prevails, but the market has come to a halt because of the long continued uncertainty regarding the purchases to be made by the Government and its allies, and the price to be paid. Nothing is yet known regarding these all-important facts, but it is believed that no actual decisions have been made. Metal for future delivery is stronger with each week, most of the larger producers having nothing to sell this side of August, and not much for August and September. Early deliveries are only obtainable through second hands and small dealers. The quotation for Lake and electrolytic yesterday was 32.75c., New York, with as high as 33 to 34c. asked for spot and prompt. Third quarter, outside of July, is pegged at 30.50 to 31c., with July at close to 32c. Last quarter delivery is quoted at 29 to 29.50c. London's price for spot electrolytic is unchanged at £142 with futures at £138. "As long as the war lasts there will certainly continue to be a large demand for copper," says a prominent New Yorker. "At the present time spot copper is scarce; there is little to be had. There is a big demand, too, for copper for late delivery. The shipping industry is calling for large amounts of copper, and their demand will undoubtedly continue even after the war. We cannot tell what will happen when peace comes. Germany, however, will be a large peace purchaser."

TIN

The obtaining and the allocation of tin supplies is at present the absorbing topic. A committee of consumers and importers is being formed which is to handle the entire situation in this country, provided its personnel and recommendations are satisfactory to the Government. The allocation of tin supplies will be in the hands of this committee and not in that of British agents in this country. The main concern of the Government is that adequate supplies be obtained and that they be properly apportioned. It is believed that satisfactory

arrangements are to result from the negotiations between the two governments as to supplies, and the fact that the regulations are to be left practically to the trade, if satisfactory to the Government, are productive of good feeling and confidence. The market has been quiet the entire week, with price-fluctuations within a range of less than 1c. per lb. Yesterday the quotation was 60.62½c., New York. On Monday it was 60.75c., and on Thursday and Friday last week it was 61c. with sales at 60.50c. reported on Wednesday, June 6. Business in general has experienced a check due to the negotiations referred to, and to the duty question, which still hangs fire. More interest is shown in far-off tin, even at present high prices, but there is not much buying. There was a moderate business late last week in future shipments from the East. Arrivals up to and including June 12 were 540 tons with the quantity afloat 3356 tons. The London market is a little lower and quiet, the quotation yesterday for spot Straits having been £236 5s., a decline of about £3 from that of a week ago.

LEAD

Spot lead sold yesterday in New York as high as 12.50c. The market is, however, quieter but very strong. Prices continue to advance. The American Smelting & Refining Co. advanced its quotation twice in the past week. On June 6 it announced 10.50c. as its quotation, and on June 8, 11c., bringing the price a little nearer to the outside market, which also went higher, or to 12c., New York, and 11.87½c., St. Louis, yesterday. A meeting was held in Washington Monday at which it is believed the Government's needs for July and beyond were made known and provided for, but the quantity and price are not known publicly. Considerable interest is attached to this and the facts are eagerly awaited. Re-sale lots are fewer now than a short time ago. While consumers are in need of metal, they manifest no desire to buy, and are proceeding slowly. Reasonable offers, however, would probably be accepted despite the fact that supplies are really scarce. For July and August, 11.87½c., New York, has been bid, but no business has resulted.

ZINC

More or less confusion prevails regarding purchases of spelter by brass makers in particular who have Government contracts which have recently been awarded. There have been several inquiries for fairly large quantities of brass and other spelter. One of these resulted in a purchase of a goodly amount and soon after the sale had been made the purchaser was notified that the Government would furnish the metal and he was compelled to sell what he had bought. Another consumer was in the market for spelter for use in meeting a contract for one of the Allies, but was compelled to relinquish an option on a large block of metal owing to inability to learn whether he or the Government was to obtain the spelter. Because of such instances and other uncertainties the market is at a standstill and practically stagnant. Prices remain unchanged from last week with future delivery metal higher than prompt and nearby. The quotation for the former is 9.50c., St. Louis, or 9.75c., New York, with the latter obtainable at about ½c. lower, in some cases at the same price. The belief continues that ultimately a large Government demand, direct or indirect, will develop so that higher prices will result, or at least not lower ones.

ANTIMONY

Because of lack of demand the market has fallen in the past week until Chinese and Japanese grades are obtainable at 20.50 to 21.50c., New York, duty paid. The market for future shipment is more active, and one estimate places the sales for May to August shipments from the Orient at 700 to 800 tons.

Book Reviews

BRAZIL TODAY AND TOMORROW. By L. E. Elliott, F.R.G.S. The Macmillan Co., New York, 1917. Illustrated, pp. 338, index. Price, \$2.25. For sale by the MINING AND SCIENTIFIC PRESS.

Brazil is a land of tremendous opportunity, with a future that is gradually coming to be understood in the United States. Its development has been slow, partly because of the commercial isolation imposed upon her during the colonial period, partly because she has not possessed the kind of mineral wealth that leads to a rapid influx of population with its reciprocal influence upon agricultural development, and finally because the difficulties of colonization, always present in a forested country, have been exaggerated in her case by a stupendous luxuriance of woodlands that have practically defied the ax of the pioneer, and which only long periods of gradual attrition can overcome. Nevertheless, this great virgin territory will in time be subdued to the service of feeding a world of nations more advanced in their manufacturing activities. Brazil is one of the great potential granaries of the earth, with an area equal to that of the United States, of which at least half is as well adapted to northern races as are the Gulf States in our own country. We have left so far behind us the early pioneer perils of the South Atlantic States that it is hard to realize the effect that clearing and draining of the land has had in making it salubrious, and that scarcely more than 150 years ago the Carolinas and Georgia were reputed to be particularly fatal to Europeans. The picture of Brazil presented by Mr. Elliott is brilliant and attractive. He is a competent observer, and approaches his subject as a man should, with enthusiasm, and with a critical but sympathetic understanding of the Brazilian people whom he describes. The introduction to the volume is unfortunate, but the worth of the book must not be judged by the bungling style of these first few pages. Once fully launched upon his treatise the author marshalls his facts in an orderly and incisive manner. He gives vivid pictures; his story of the political development of the country is swift and strong, the account of Dutch and English efforts at conquest and domination are interestingly presented, and the narrative of the strange adventures of the bandeirantes in their struggles to explore and exploit the great interior sertão is an impressive tale of one of the most peculiar and thrilling colonization-movements that the Western Hemisphere has witnessed. The later colonization from Europe is not dwelt upon at great length, and one will fail to find a full history of the turmoil and trouble brought about by the German immigration into the southern states of Brazil. The turbulence brought into the politics of the nation by these 122,000 Germans and their descendants, with the disasters attendant upon their ceaseless revolutionary attempts, is out of all proportion to their numbers, and the contrast between their influence and that of the other alien populations is noticeable when it is considered that the world has barely heard of the 104,000 Russians who settled in Brazil, nor of the 1,360,000 Italians who have found home and prosperity in that country without disturbing the established social order. Mr. Elliott has written a readable handbook of the republic, which should be the *vade mecum* of every visitor, and should be read by all who are desirous of knowing the characteristics and the outlook of our South American neighbors. Mr. Elliott discusses social conditions at length; points out the remarkable fact, known to all who are thoroughly acquainted with the country, that the Brazilians have no such inherent tendency to revolution as is found in some of the Spanish-Americans, and hence that Brazil may be regarded as having a stable government under which industry may find protection; he gives an excellent account of transportation facilities, and of the dominant in-

dustries; discusses the currency, banking, and investments, the Federal, State, and municipal debts, and the sources of revenue. Other chapters deal with natural products, and commercial relations. He has caught the romance of the rubber industry, and he reveals the short-sightedness of the Government in its restrictive policy, crushing the rubber business under excessive export taxes, a blindness equalled only by that of the great rubber merchants who took no steps to develop the planting of orchards to insure a continuance of the output at a time when they might have succeeded. Instead of such a wise forward vision, they remained content to make their brokers' commissions on the dwindling supply, and laughed at those who proposed to rationalize the industry, while the problems of cultivation of the rubber tree (*Hevea brasiliensis*) were in the meantime being worked out in Ceylon, leaving the Amazon valley finally in nearly the same position with regard to this natural product that the scientific culture of cinchona in Java left improvident Peru. Mr. Elliott has taken only a glancing shot at the mineral resources of Brazil. He barely mentions the St. John del Rey, the deepest gold mine in the world, and one would never guess from his account that the State of Minas Gerães has the largest untouched deposits of bessemer iron ores in the world, nor that the United States is more dependent upon the manganese mines of the same remarkable State than we like to admit; but the emphasis of the book, nevertheless, is laid on the agricultural riches of the country, where it properly belongs in view of their preponderance. It must be remembered, however, that immense areas of Brazil are so covered with jungle and with deep soils, that the mineral possibilities are at best but imperfectly known, and that geologists such as Orville A. Derby and Dr. John C. Branner have given reasons for belief in the ultimate development of such resources on an important scale.

TUBE MILLING. A Treatise on the Practical Application of the Tube Mill to Metallurgical Problems. By Algernon Del Mar. Pp. 159. Ill., index. McGraw-Hill Book Co., New York, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$2.

This enjoys the distinction of being the first work on tube-milling ever written. It is prepared by an engineer of wide practical experience in milling, who has acquired his knowledge by personal application in obtaining economic results, supplemented by wide and appreciative study of the multitudinous contributions on the subject in technical periodicals and in the bulletins of engineering societies. It brings together significant data drawn from the experience of metallurgists all over the world, discussed by a discriminating critic in the light of his own work. It is a handbook of details, presented in orderly manner, that must prove useful to designers of new plants and to engineers in working out their efficiency-problems. Mr. Del Mar is fully aware of the present limitations of ball-mills and tube-mills, and he states that "every variation of shape and every means of screening to attain capacity with the least expenditure of power" is being investigated by mechanical and metallurgical engineers. The tonnage per horse-power in tube-milling varies from 1 to 2.5, and the latter figure is far above the average. Variations in the character of ore, size of material fed, fineness of crushing, and many other factors, enter into this result, yet it is evident that the output is not great in comparison with the power required. In general it may be said that under what may be regarded as average conditions as to character of ore, and cost of power and supplies, the cost per ton when grinding to about 100-mesh is above 30 cents. In exceptional cases it is reported as low as 10c., and Mr. Del Mar discusses an unusual case at the Gold Hunter mill in Idaho where a feed with 94% of plus 35-mesh material was ground to a discharge containing 30% of minus 200-mesh pulp at a cost of 7.3c per ton, this including consumption of pebbles and lining, repairs, and power. Improvements in tube-milling that would reduce the cost on

average hard ores to 20c. per ton or less would open up enormous possibilities in the treatment of low-grade ores.

Mr. Del Mar describes in considerable detail all the well-known mills, the Abbé, Herman, Chalmers, Hardinge, Marcy, 'Compeb,' and Marathon, and he explains the special functions of the different types in grinding for concentration and for cyaniding, making comparisons illustrated by screen-analyses of the products. He also goes into detail concerning the factors that govern capacity, the heat generated in crushing, the relation of coarse to fine ore in giving capacity, and the influence of variation of feed upon efficiency, as well as the proper dilution of pulp to obtain the best economic results. The book gives abundant data regarding the El Oro, Globe, Osborne, Miami, Komata, Liberty Bell, and other liners; feeding and discharge devices; power requirements; details of mounting, foundations, and other practical matters which are important in operation. One chapter is devoted to amalgamating in tube-mills, and another to grinding for flotation. It is an eminently useful and usable book, that will commend itself to engineers and mill operators.

TIMBER FRAMING. By Henry D. Dewell. Pp. 272, with index. Well illustrated. The Dewey Publishing Co., San Francisco. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$2.

Every mine manager and superintendent is interested in anything that has a practical bearing upon the business in which he is engaged. Frequently it is necessary to design and build surface-structures at mines. Ore-bins, mills, head-frames, trestles, flumes, and variety of other structures are required from time to time, and when such occasion arises, it usually devolves upon the superintendent to prepare a design for the proposed building, or whatever it may be, that is wanted, particularly at the smaller mines where there are neither civil nor mechanical engineers on the staff. Then it is that a knowledge of how to go about the job becomes necessary. The kind of timber to employ for various purposes, the calculation of the stresses that will be set up in the structure when completed, and in use, and how properly to meet them by suitable design and joining of the several parts, these and other equally important questions have to be anticipated and provision made to meet them. In such an emergency this book will prove of great value. It is desirable that the structures be as simple in design as possible, while meeting the demand for safety and efficiency. There is a very common lack of the appreciation of the strength of timber-structures properly framed, and this usually results in much unnecessary expense and waste of materials by building a structure in which the timbers are of far greater size than the condition demands, and in employing numerous members where none at all are required. Fortunately, however, the novice in timber-structure design usually errs on the right side—he seldom builds a weak one. By knowing how, the designer builds neither too expensively, nor is his structure weak. It is in the determination of these questions that Mr. Dewell's book will be of value. He has had large experience in the design and building of structures consisting principally of wood, and a study of his methods, as described in 'Timber Framing,' cannot fail to prove of great value to those lacking practical experience in this particular line of work, but which can be readily acquired by a study of this instructive book.

The chapters on working-stresses, washers and pine, joints, trusses, columns, and splices are particularly good; also that on foundations. Some space is given to the design and construction of head-frames, flumes, and ore-bins. The last chapter is devoted to specifications for timber framing, which appears to be complete. The book has been prepared with care, not so much for the engineer experienced along these lines, but rather for the practical man who desires also to know. It is a book that will undoubtedly meet with a large demand.

Mining Decisions

GRUBSTAKE CONTRACT—THIRD PARTY INTERESTS

Where a prospector grubstaked by plaintiff was accompanied on a prospecting trip by a second prospector who was grubstaked by his mother, and who had agreed to share with the first prospector any locations made under the grubstake contract with plaintiff, the mere fact that the first prospector assisted the second in making certain locations in the name of the latter and his mother would not entitle plaintiff, who had no contract with the second prospector, to claim any rights in such locations.

Turner v. Wells (California), 238 Federal, 766. February 13, 1917.

TUNNEL EASEMENT—DUMPING PRIVILEGES

Defendant acquired by right of way deed the right to use a tunnel in plaintiff's mine and to extend the same into his own claim. In an action to recover damages for his dumping of waste rock upon the surface of plaintiff's claim, it was held that the deed did not by implication give defendant such rights unless he could not without unreasonable inconvenience and expense, obtain dumping privileges elsewhere in the operation of the tunnel.

Himrod v. Ft. Pitt Mining & Milling Co. (Colorado), 238 Federal, 746. January 26, 1917.

TUNNEL EASEMENT—EXTINGUISHED BY PRESCRIPTION

Where plaintiff's predecessors in interest in early days acquired an easement for a mining tunnel through property owned by predecessors in interest of defendant and thereafter suffered defendant's predecessors and defendant to use the tunnel as a water tunnel for more than 20 years, openly, notoriously, and continuously, the easement was extinguished by prescription, irrespective of the means by which it was originally acquired.

Wall v. United States Mining Co. (Utah), 239 Federal, 90. December 1, 1916.

OIL LEASE—LESSEE'S OBLIGATIONS

When the lessee of a tract of land for the production of oil and gas has paid an adequate consideration in cash and has complied with the only obligation expressly required of him during the first year after the signing of the contract, by the drilling of one test well, and has not found oil or gas in paying quantities, the grantor is not entitled to a cancellation of the lease on the ground that the lessee failed to perform an implied obligation to drill more than one well for the common advantage of the lessor and lessee.

Nabors v. Producers' Oil Co. (Louisiana), 74 Southern, 527. March 12, 1917.

STATE LANDS—MINERAL LOCATION OF IN OREGON

A person locating as mineral land school land owned by the State of Oregon acquires only a temporary possessory right, subject to divestment by failure to purchase or lease the lands as required by the State law from the State land board. Where plaintiff assisted defendant in entering and leasing a mining claim actually within his own staked claim, and later, when defendant struck pay ore, admitted in the presence of witnesses that the claim belonged to defendant and offered to buy it, plaintiff was estopped from claiming the property as his own. An interest in a mining claim must be created in writing and cannot be created by verbal option.

Grand Prize Hydraulic Mines v. Boswell (Oregon) 162 Pacific, 1063. February 6, 1917.

EDITORIAL

T. A. RICKARD, Editor

ALUMNI of the Colorado School of Mines will be sorry to learn that Mr. H. C. Parmelee has been compelled to resign his position as President of the School, on the vote of the three trustees that are not alumni. Our opinion of the fitness of those trustees for their duties was expressed in these columns two weeks ago.

FOUR million persons subscribed three billion dollars toward the Liberty Loan. Among them the country owes a hearty vote of thanks to the bankers, who not only contributed of their funds but also gave services of a most useful kind to the work of collecting subscriptions. Our moneyed people are behaving very well in these great days.

MINING is playing its part in the War, as everybody knows by this time. We received a letter the other day from the Assistant Inspector of Mines, not at Butte or at Bendigo, but 'somewhere in Flanders'. The object of this mining was not so many ounces of gold or pounds of copper per ton but so many of the enemy per cubic yard of blasted ground. The gallant Major that occupies the responsible position just mentioned is well known to students of the peaceful art of mining, from Johannesburg to New York. His useful work at Messines was accomplished by the use of that new explosive, ammonal, in the manufacture of which a metallurgical neighbor of ours had won frequent publicity.

AMONG recent patents for methods of flotation we note No. 1,228,184, of May 29, 1917, issued to Mr. Henry P. Corliss, the joint author of the excellent article appearing in our issue of June 2. Mr. Corliss is not tied to Minerals Separation; he has assigned his patent to the Metals Recovery Company, of New York, with which Mr. W. B. Thompson is identified. He uses nitro-naphthalene, either alone or with oil, as his frothing agent. This substance is non-oleaginous and solid, but can be dispersed in the pulp so uniformly as to perform its frothing function most efficiently. Only a quarter of a pound of it need be used. The nitro-naphthalene is recoverable from the froth and can be re-used for the treatment of fresh ore. Remarkable results have been obtained with the use of this substance in the Magma mill, in Arizona.

OUR CORRESPONDENT at Cobalt, Ontario, tells this week that an order in council has been passed by the Provincial government relieving the holders of mining claims from the performance of assessment-work for the year 1917. The order is not for absolute exemption, but

grants a year's extension of time within which to do the statutory work. It might be well for us to take note of the thoughtful consideration extended by Ontario to its miners, and to follow suit in some appropriate manner. At the prevailing extravagant cost of supplies the required \$100 worth of work would not make much of an impression in effective development this year in any event. It has been suggested that enlisted men, at least, should be exempt, which appears to be no more than common justice. We venture to add that when the next call for subscription to government bonds is made in September, the law might provide for accepting the purchase of a bond in lieu of the annual assessment work, but without counting it in the total of the \$500 worth of work demanded as an antecedent requisite for the obtaining of patent.

EMULSIONS are of supreme significance to the flotation metallurgist, now that the colloidal dispersion of oil in mill-pulp, and its subsequent breaking so as to oil the bubbles, has become a 'critical' question in the great litigation between the patent and the art. Every contribution to our knowledge of the subject therefore is welcome, and the article on 'Physical Chemistry of Emulsions' appearing on another page of this issue will prove of great interest, coming as it does with the authority of such a distinguished scientist as Dr. Martin H. Fischer. His insistence upon the importance of using all the water in the formation of a colloid hydration compound in preparing a 'permanent' emulsion throws light on the function of the contaminant in flotation, especially as related to the equally necessary condition of breaking the emulsion in supplying oil when needed for oiling the bubble-film and the mineral-particle. Dr. Fischer's reference to the characteristics of casein, with either acid or alkali, as a stabilizer of oil-emulsions, and the conditions under which such an emulsion breaks; is also suggestive.

IT WAS Dr. Raymond, we believe, who first said that we might ask 'Who's Who'? but not 'Who's Hoover'? Assuredly we mining engineers need ask no such question, and yet, in a deeper sense, a great many that know Mr. Hoover only slightly must have asked themselves now that he has become so famous just what kind of man he really is. To them we commend Mr. Will Irwin's article in the current issue of the *Saturday Evening Post*. Mr. Irwin's appreciation is called 'The Autocrat of the Dinner Table', and it is well done. They were at Stanford together and the trails of the reporter and story-writer have crossed those of the engineer and financier so often during recent years that the one is well able to

do justice to the other. Something to criticize of course there is—such as the “new processes” that the young American introduced in Australia and the repeated reference to the head-hunters of Borneo, meant probably for the development of the Bawdwin mines in Burma—but we refer to these slips only to emphasize our own knowledge of Mr. Hoover’s mining career and then to second most cordially the stress laid by Mr. Irwin on the dominant note in Mr. Hoover’s character: sincerity. It is the sincerity of his purpose that has enabled him to over-ride opposition in the highest quarters when engaged in his great Belgian benefaction, and to the same fundamental quality he will owe his success in overcoming such opposition as he is now facing before Congress. This sincerity of purpose is another phase of the intellectual honesty that made him so efficient as an engineer and so successful as an organizer of big enterprises. And through the complex fabric of his personality there run golden threads—nay ribbons—of generosity. Long before the children of Belgium learned to associate his name with charity or the refugees from his own country found assistance at his hands, he had given expression to his innate kindness by assisting those in distress, often the less fortunate members of his own profession. His sympathy with suffering was no trait developed on the approach of German brutality; long before the War it was a winning weakness of which his personal friends were well aware. So also his large interest in public affairs and his intensely patriotic interest in American affairs. He has been in our mind when in recent years we have spoken of engineers that found time to be good citizens and of metallurgists that could spare time to broaden their culture. But we must stop. Read Will Irwin’s story.

Control of Coal and Transportation

There has been oppressive silence in the newspapers regarding the recent radical recommendation of the Federal Trade Commission to Congress, proposing that the United States Government should take possession of the sources of coal and coke in the United States, and operate them through a Government agency, and also that the transportation systems of the country, both rail and water, should be “similarly pooled and operated on Government account, under the President, all such means of transportation to be operated as a unit, the owning corporation being paid a just and fair compensation, which would cover their normal profit, upkeep, and betterments.” The first news was ‘featured’ in the evening papers, but it occupied an inconspicuous position in the morning papers the day after, and the matter has since been carefully shielded from the public gaze. A few remarks have been made to the effect that this tended toward communism, and that it should be branded as socialistic, which we admit would be a reproach. We believe that Socialism means, in the last analysis, the denial of individual initiative, but we do not see that the Government administration of the

transport systems involves a denial of the individual initiative; therefore we would not call it socialistic. We believe that the Socialists have developed some good ideas, which should be utilized without regard to their parentage for the betterment of government, but this is very far from accepting a socialistic programme, which at bottom, we believe would tend toward intellectual stagnation and prove injurious to organized society. It is well to recognize that the railroads are so vital in our social system, and are so necessarily subject to Federal supervision in order to ensure just and equitable treatment, that they have always possessed chartered prerogatives of eminent domain that partake of the nature of sovereign powers. There was a time when men had to send their letters by special courier, or pay private individuals and associations of individuals for transporting them. It would seem absurd in these days to undertake to manage a nation’s correspondence in any such bungling manner. There was also a time, not long past, when it was the custom to grant franchises to private corporations for building highways, including the right to collect toll. We know what people would think in these days of turning over the highways to private toll-collecting corporations. The report of the Federal Trade Commission indicates that it has been discovered that the coal mines are involved to an intolerable extent in inefficient methods of production and that the railroads are inadequately equipped for transportation and scientific distribution of products, and furthermore that, locked up in the system as it now stands, there exists the evil of unbridled speculation detrimental to the public welfare at all times, and imperilling the nation in time of war. These charges have been frequently hurled at the railroads and the coal ‘barons,’ and they now meet with confirmation from a source of such character that it must be respected. Under Government control the railroads could be made to serve as a regulator of manufacturing operations and a balance-wheel of industry. When times are dull and prices correspondingly low the Government could avail itself of the opportunity to carry forward betterments and renewals of permanent way and rolling-stock, thus tending at the same time to improve financial conditions. When business was active the railroads, under such intelligent direction, would not be under the necessity of intensifying the upward trend of prices by coming forward with large orders for equipment in order to meet the demands of an increasing traffic. Today the railroads are practically in the hands of the Government through the regulation of rates and other control of operations as exerted by the Inter-State Commerce Commission. The Congress has regulated wages, and the workmen themselves practically determine the time-tables and length of run by train-crews. Unification of management would reduce enormously the overhead cost, by obviating the existing duplication of officials, agencies, and terminals. Solicitation of business, another costly item, would disappear; and restriction upon the use of cars beyond single railroads would be avoided. Expropriation would be unnecessary

to carry into effect a complete scheme of nationalization. The Government's guarantee of interest on outstanding bonds and of normal dividends on stock would strengthen the position of all such securities in the market, and fully satisfy the rights of ownership, since the value of ownership as a source of income would be conserved; it is merely the opportunity for flamboyant financing through control of proxies that would be eliminated. The interests of the real owners, the stockholding public, would be protected not alone in the certainty of dividends, but in exemption from the perils of speculative manipulators. Instead of conceding the addition of 15% extra to existing freight-rates it might be well to relieve the distressed officials from further worry by letting the Government struggle with the problem.

The Miami Appeal—II

In our last issue we summarized the two opinions of the Court of Appeals at Philadelphia. More remains to be said. The majority opinion includes sundry references to the technology of the process that call for respectful demur. Judge Woolley, for example, says that the patent is based upon "a discovery that the affinity of oil for metal is greatest and the metal recovery highest when the proportion of oil to ore is relatively least." Can the "affinity" of oil for metal vary? Physical forces are constant. Is not the use of oil proportioned to the 'mineral' in the ore, not to the 'ore,' which includes both gangue and mineral? It is unfortunate that the Court should have been misled into publishing a statement that the recovery is highest when the proportion of oil is least at a time when several plants, working on a scale of 1000 tons per day, or more, and using a maximum proportion, over 1%, of oil, have obtained results as good, or in some instances better, than those obtained with a fraction of 1%. Judge Woolley states that before froth-flotation was discovered there were only two processes that had "reached the commercial stage"; he mentions the Cattermole and the Elmore bulk-oil methods, ignoring the fact that Elmore's vacuum method, using air as a floatative agent, was far more widely used, and more nearly a "commercial" success, than either the Cattermole granulation or the older bulk-oil process. He describes Froment's method as one dependent upon a thorough oiling of the mineral and using agitation "for the sole purpose of causing the metal particles to rise", although, if we remember correctly, Froment, in his patent, laid emphasis on the formation of a gas for the production of bubbles, rising to the surface, "where they form a kind of metallic magma", or a mat of mineral-coated froth. Referring to 'the' discovery, namely that supposed to have taken place in the Minerals Separation laboratory in March 1905, the learned Judge says that "its great value, especially in zinc and copper ore concentration, met with world-wide recognition. The art immediately adopted it and paid tribute to it." If we are correctly informed, the first attempt to use froth-flotation was not made in the United States until 1911—

six years after patent 835,120 had been granted—and the first plant designed under the supervision of Minerals Separation in the United States was built in 1913—eight years after the supposedly epochal event.

In regard to the so-called 'critical' proportion of oil: the idea of such a point was prompted probably by the imperfect emulsification of the oil, the excess of unemulsified oil in the pulp being a deterrent to successful frothing. There is a true critical proportion of oil that can be permanently emulsified in water, and Mr. William C. McC. Lewis has determined this to be approximately 2% in the case of mineral-oils. As our readers are aware, several of the large copper-concentrating mills have been using 22 or 23 pounds—more than 1%—of oil successfully, obtaining even higher recoveries than when using small fractions of 1%. But the use of the larger proportion is wasteful, therefore only 10 pounds of oil per ton is being employed now, because that suffices to avoid conflict with the claims made by the Minerals Separation people, whose counsel, before the Supreme Court, stated that the supposed beneficial effect of using less oil began when the proportion was under 0.5%. Apparently, therefore, the use of this proportion of oil in a pneumatic cell would comply with judicial requirements. By the way, sundry licensees of Minerals Separation are using the pneumatic type of flotation machine; if the Philadelphian decision is made good it would appear as if they would have to settle with the owners of the Towne and Callow patents, covering the use of porous media for aeration. For some ores the violent agitation of the Minerals Separation blade-impeller machine is best, for others the quiet aeration of the Callow cell, and for others again it is found advantageous to supplement one method for another when re-cleaning the concentrate. That brings us to the preliminary mingling of the oil in the pulp previous to admission into the froth-making machine. Apparently it will be necessary to comply with the Philadelphian decision by using some such method as appears in 'the prior art'. Will a bucket-elevator come within the prescribed limit? Minerals Separation has patented the Chapman idea of oiling the pulp in a grinding-mill. We are informed, however, that the use of modifying agents in a tube-mill is not new because it was disclosed in a patent for crushing guayule issued to H. T. G. Vanderlind, No. 979,902, in 1910, whereas that of G. A. Chapman is No. 1,102,874 of 1914. It is unlikely that the Courts can be induced to decide that all kinds of mixing or stirring constitute an infringing agitation, in view of the terms of patent 835,120, in which one kind of agitation is so carefully specified. We suggest that, since the point of public interest is to introduce emulsified oil into the pulp without previous violent agitation, this emulsification of the oil in water can be accomplished in vacuum as well as in the atmosphere, and may be attained also by other means.

In the meantime there is that "soluble frothing-agent" of patent No. 962,678, which has been sustained at Philadelphia. This one also is tied, like No. 835,120, to a violent and persistent type of agitation. Therefore it

would seem that mill-men would be free to use either a soluble or a non-soluble agent in a pneumatic cell. Meanwhile the various laboratories have ascertained that the presence of a soluble frothing agent is not essential to flotation. Pine-oil, when pure, is insoluble and the pure varieties of the creosote series are likewise insoluble, although the commercial varieties of these products are not pure and cannot be made pure within reasonable limits of price. The patentees apparently had in mind such agents as were in major proportion actually soluble in water and they should not be able to prevent the use of agents that contain only a relatively small quantity of soluble fractions of an accidental nature, because in the fractional distillations it is impracticable to make any particular fraction pure without going to prohibitive cost. Incidentally, we may refer to the curious remark made by Judge Woolley in regard to inorganic frothing agents. He suggested that two of the claims of patent 962,678 "cover inorganic frothing agents also," although he said that he knew of no such agent. Would it be respectful to describe this remark as supererogatory? Are all oils of organic origin? What is an oil? Perhaps the learned Judge or one of his colleagues in another court will have the privilege of answering this conundrum also.

Price Regulation

Two wholly distinct ideas are before the public relative to commodity-costs. The result is confusion. There is talk of price-control; there is also talk of profit-limitation, of the sort that is seen on contracts proposed and completed for ships and arms and motors and a host of other equipment that the Government is to obtain at cost plus 10%. The public has been vaguely under the impression that 'cost plus 10%' involved cost-control. It does nothing of the kind. The cost may be anything at all; under such a contract it makes no difference to the manufacturer how high the market-value of raw material may mount; or, looking at it from another angle, which no intelligent manufacturer could be expected to ignore, the higher the cost the larger the commission, by applying the simple rule of 10%. The question of real interest to the public is the limitation of costs; limitation for the sake of every consumer whether he be a humble workman earning \$2.50 per day, or Uncle Sam borrowing \$2,000,000,000 to spend again in the purchase of munitions. It has been said that high costs mean circulation of more money, therefore re-duplication of profits, and again, in natural sequence, widely distributed gains. This has the doubtful merit of all half-truths. It applies to one class of mankind, namely, to the man who produces or manufactures or sells for his own account. The hireling, save in a few cases where an equitable sliding-scale governs his pay, is the one that bears the larger burden of the extra cost. Since the fundamentals of human necessity are food and shelter, and since the more insistent of these is food, the cry for food-control that has stirred Congress is understandable, but Congress has muddled into the solution of the problem

animo non astucia. This blindness to the larger issue is the legitimate result of distress caused by the unconscionable increase in food-prices. The increase since last October, expressed in percentages, is shown by a table printed in the Congressional Record on May 12, from which we take a few items. Oatmeal has advanced 33%, navy beans 111%, split peas 71%, chuck roast 46%, ham 29%, potatoes 138%, and onions 186%. Meanwhile, to view another aspect of the case, the profits of the American Can Co. in 1916 were approximately 200% above those realized in 1914; of the Bethlehem Steel Company 680%; of the Crucible Steel Company 1200%; Phelps-Dodge Corporation 230%; the American Smelting & Refining Company 150%; and the net revenue of the railroads of the United States had risen from \$275 per mile in 1913 to \$550 per mile by October 1916, since which time there have been further advances.

The great issue, to obscure or neglect which is to trifle with the needs of the Government and of the people in our preparation for war, is to regulate prices, not merely food prices but metal prices, and prices of every other commodity. It may not be strictly democratic to deny a man liberty to do what he will with his own and to ask what price he please for the product he may have to offer; but back of that lies the true spirit of democracy, which is equal treatment for all citizens. All men must be dealt with alike; no discrimination must be tolerated; no class legislation can rest upon the statute-books. That is so cardinal a constitutional principle that it is surprising to witness so little constructive criticism in Washington upon the various food-control bills that have been introduced. A few weeks ago when metal-price regulation was in the air the metal-producers held out as their chief argument in opposition the merry disturbance that would follow an attempt to govern the prices of foods, which they insisted would be involved along with metals in an attempt at price-control. They were perfectly correct in their view of the equal rights of all producers to be treated alike. We believe that the country is wasting precious time by not facing the whole problem of regulating commodities. One part is no more complex than another, and the laws must be just or they will provoke friction and delay; they must be constitutional or they will soon be reversed by the highest tribunal, suddenly throwing commercial relations out of adjustment, with consequent economic consternation. With bessemer pig-iron selling at \$53 per ton it is clear that regulation of the steel and iron trade would be a public good; with copper selling to the Government at 25 cents and costs of production standing at about 12 cents, it is plain that some beneficial adjustment might be made; with lead selling at 12 cents and carried on the producers' books at 3.88 cents, it cannot be urged that potatoes are high-priced. As the metal-producers remarked, "if you regulate metals you must also regulate foods," and that is a good text for a wholesome democratic homily. While we are fighting for democracy let us not fail to keep our own democratic national platform from collapse.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes expressions of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Nitrogen in Metal Mines

The Editor:

Sir—My letter that appeared in your issue of May 26 on the occurrence of nitrogen in a bore hole on Pender island, Strait of Georgia, B. C., in which I suggested that some light about the nature of the formation might be thrown by Mr. Robert A. A. Johnston, author of 'A List of Canadian Mineral Occurrences,' has brought me a letter from that gentleman, in which he informs me that the occurrence was reported to him by Mr. William Fleet Robertson, and that he was writing to him requesting that he communicate with either your or me on the subject. Mr. Robertson chose the latter course, and I enclose his letter.

F. H. MASON.

San Diego, June 13.

[Mr. Johnston says that "gas of this kind might become useful in the manufacture of synthetic ammonia," but Mr. Robertson is of the opinion that the idea "does not appear to be commercial." He corroborates the analysis of the gas.—EDITOR.]

Cost of Cyanide

The Editor:

Sir—Referring to a recent comment on the price of cyanide in Canada made by the Cassel Cyanide Company through arrangement with the British government, it is not correct to assume that all of the cyanide used in the mines of Ontario is supplied f.o.b. Ontario points for 15 cents per pound.

On the 21st of October, 1914, the Cassel Cyanide Company offered a three-year contract to the mines of Northern Ontario as follows: "Entire consumption of cyanide at the company mines until December 31, 1917, beginning January 1, 1915, delivery, c.i.f. South Porcupine, Ontario, ocean war-risk for buyer's account, price 18c., basis 100% for high-grade sodium cyanide, until June 30, 1915; to the end of 1916, 16c., to the end of 1917, 15c. If buyers prefer 98 to 100% cyanide, sellers will endeavor to deliver this quality, the price of the same to be 1c. per pound more."

Then followed an estimated quantity which would be consumed by the mine during this period. As the price mentioned in the contract covers cost, insurance, and freight, but not ocean war-risk nor duty, there is approximately 1c. per pound to be added to the above figures.

Some of the mines exceeded the estimated consumption to a considerable amount and have been obliged to make new arrangements for their current requirements. Others did not enter into the contract and have been

obliged to purchase their cyanide under current quotations from the Cassel Company. During the month of May, 1917, the net price of sodium cyanide, so-called 129% grade, landed at South Porcupine, was 33.7c. This is probably the price at which all cyanide will be sold in Ontario after December 31, 1917, unless existing conditions should materially change in the meantime.

New York, June 14.

Mines in Granite

The Editor:

Sir—Would you kindly answer in your paper the following question: Is there any truth in the often expressed opinion that metalliferous veins in granite are not persistent in depth or strike? Also are there any deep large mines wholly within granitic rocks?

CHAS S. BOONE.

San Francisco, May 29.

[Granite is considered by many as an unfavorable rock in which to look for permanent mines. That there is no sufficient warrant for this prejudice is shown by the fact that many profitable mines of gold, silver, and copper occur in granite. The Granite Mountain mine at Philipsburg, Montana, is in granite. It produced \$25,000,000 yielding a large profit. The great copper mines of the Butte district, Montana, are in grano-diorite (a variety of granite), and these mines have paid hundreds of millions in dividends. The Empire mine, and all of the lower part of the North Star mines at Grass Valley, California, are in granite, and are both deep and profitable. The Black Oak mine in Tuolumne county, California, is over 1800 ft. deep, wholly in granite, and also profitable. The Soulsby and Confidence mines, likewise in Tuolumne county, are entirely in granite and have profitably produced precious metals to the extent of \$6,000,000 and \$5,000,000 respectively. Many more examples might be given. The prejudice to which our correspondent refers is the result of multitudes of failures that have attended the development of gold-bearing and copper-bearing pegmatite dikes and dikes of pegmatitic quartz, which are common in granitic areas. Pegmatitic quartz-dikes are almost universally mineralized to a small extent, that is, they contain sulphides and rare metallic oxides, and usually some gold, that crystallized out of the final silicious residual liquor upon the consolidation of the granitic magma. The mineralization in such cases is seldom uniformly disseminated; the tendency is toward isolated patches of enriched rock, with lean masses between. In many cases, however, such original dikes formed weak zones along which faulting

occurred later, followed by mineralization through the agency of ascending hot solutions sometimes forming valuable veins. Therefore it must not be inferred that the existence of pegmatitic quartz is in itself unfavorable. It is a question of the interpretation of the geologic history of the special deposit.—EDITOR.]

Sampling Large Low-Grade Orebodies

The Editor:

Sir—There has been nothing in recent years in the mining world that has attracted as much attention as the testing, development, and promotion of the Alaska Gold Co., and the results obtained when working upon a basis of 12,000 tons daily; the best engineering talent was brought to bear upon the problem before the property was offered to the public, yet the resulting recovery of valuable mineral failed to equal the estimate made. Cost estimates and flow-sheet were correct, showing that good judgment had been exercised in those fields. The failure, as we know, was due to faulty sampling, yet can one say, when over 300,000 tons of ore has been milled for a sample, that human foresight could offer a truer solution of the question of value per ton of the ore? The answer, it seems to me, lies in the possibility that this great tonnage must have been more or less selected. Was the entire ore-zone cut through and milled from wall to wall? Was it done in a number of places *as a test*? Was it not that certain stopes were started and mined for the mill-test? Those in charge know; I do not. Some years ago I was called upon to report upon a mine in south-western Colorado, claimed to have 5,000,000 tons of pay-ore, but which, after operating on a basis of 300 tons daily, failed to pay. The ore-zone was claimed to be from 50 to 60 ft. wide and 800 ft. long. Upon the main level, five cross-cuts were carried through the ore-zone from wall to wall. To determine the value per ton of the ore, I caused chip or moil sampling to be done in the foot-sections in each of the cross-cuts; following this, a power-drill was used to slab off a thickness of approximately 3 ft. of the ore, when the process of moil sampling was repeated on the freshly broken face. The ore from the 3-ft. cut, amounting to about 60 tons for each cross-cut, was sent to the mill, when it was crushed, sampled, and milled. The value of the ore was less than \$3 per ton, but the three samplings, that is, the two moil-samples and the return from the mill, checked each other within 10c. per ton. It appears to me that under normal conditions of mining gold, silver, or lead-bearing veins, the foregoing method will come as close to a fair degree of accuracy as can be expected from mining operations. The sampling of orebodies never can be carried to absolute accuracy; at best it is an approximation, even where the most extreme caution is taken to prevent the human element influencing the final result.

To the young engineer engaged in sampling low-grade orebodies my advice is to sample by moil in pre-determined lengths, based upon the assumed value, and closely inspect the assay returns. When even a small

variance from an accepted value for the orebody is found, re-sample that ground in smaller lengths, to determine the reason for that variance; then, with the fact clearly and well established that a portion of the orebody is richer than the rest, proper allowance and weight should be given to it, bearing in mind always that the ore broken in mining is sure to be lower in value than that broken by sampling. This simple fact has been so frequently stated in works on sampling that it seems out of place to state it again here, but it is a fact of vital importance in estimating the value of an orebody. Of course, if opportunity be given for test-milling, that should supplement the hand sampling, as there is no better known method of determining the saving than by subjecting properly selected parts of the orebody to mill work.

RICHARD A. PARKER.

Denver, Colorado, May 7.

The Editor:

Sir—My interest in your editorial on 'Sampling Large Low-Grade Orebodies,' and my convictions on the subject of moil-samples versus mill-tests, have prompted me to contribute to the further discussion of this interesting phase of mine sampling. I am a supporter of the moil-sample, and more than that, of the small-weight-per-foot moil-sample. I do not wish to decry the usefulness of mill-tests, nor of records of past yield, but I am convinced that in order to interpret the results of these with any reasonable degree of accuracy it is necessary that they be supplemented by moil-samples; or, perhaps, it would be better to say that it is of the greatest value to have moil-samples supplemented by mill-tests, since, if I have to depend on either method alone, I much prefer the moil-samples. I am assuming that a systematic method of sampling is employed and that the work is done by skilful men. In order to make my position clear, I should like to state a few basic principles that I believe underlie all successful estimation of standing ore by means of samples, whether these samples be mill-tests, slabs of ore broken by the aid of machine drills, heavy moil-samples averaging several pounds per foot, or light moil-samples (and this is the kind I believe in) averaging in the neighborhood of one and one-half pounds per foot. In the close of your editorial you touched so skilfully upon some of these principles that it is impossible to avoid enlarging upon the same topics, but I am rearranging them somewhat to place the emphasis rather more as it appears in my own mind, and I trust that the appearance of plagiarism will be forgiven.

The keynote of successful valuing of mines is interpretation, and this is based upon two factors: the judgment of the man doing the work, and the data on which he bases his conclusions. The first requires a natural aptitude for the work, plus sound training in the principles involved, and an experience that has seen those principles worked out. It is a mistake to assume that anyone that can cut a clean channel can sample a mine. The second requires the systematic collection and assem-

bling of reliable information. The best judgment in the world can be vitiated by deceptive data, and similarly the collection of reliable data is the first step in any process of mine valuation. There are two outstanding facts which must be evident concerning these data: they must be representative, and they must be accurate, detailed, and specific, so that when, at the end of his work, the examining engineer brings his judgment to bear upon them, he may have a full set of tools with which to work. Applying these criteria to mill-tests and moil-samples in turn:

(1) They must be representative. In this I think one may safely say that the moil-sample outclasses the mill-test. The mill-test, like the moil-sample, is representative only of that portion of the mine from which it comes, but, unlike the moil-sample, its bulk is so large that from sheer cumbersomeness it cannot be duplicated over many parts of the mine. The average of all the mill-tests made on the deposit is therefore more likely to be broadly selective, and the result in error by just that much, whereas the moil-sample can penetrate every nook and cranny of the available workings. This is the great danger inherent in mill-tests, and I believe the error due to this is far greater than that generally attributed to moil-samples from other causes, and rectified in them by a sampling factor.

(2) They must be accurate. This is where the advocates of the mill-test get in their big work. Admittedly, the small speck of accidental gold in a moil-sample weighing one and one-half pounds per foot has a tremendous effect, and also the mass of a mill-test will reduce such accidental variations to a minimum. As a single isolated result the mill-test will certainly show a tenor much more nearly like that of the mine. The presence or absence of the speck of gold will make the returns for the moil-sample jump all over the lot, but just what does that jumping amount to? Its presence or absence is purely accidental, and, as such, compensates more or less according to the law of the least squares. That is, the total error will tend to accumulate only as the square root of the number of samples, or, the error of the mean will approach that of a single sample, divided by the square root of the number of samples. I say 'approach,' because, with the wide accidental variations in samples, the laws of least squares are probably not strictly applicable. A little calculation will show that with the comparatively large number of moil-samples usually taken, the accidental errors are reduced to a point below our knowledge of other factors.

Unfortunately, this question of accuracy cannot be left with a discussion merely of accidental errors. One of the fundamental premises of compensating errors is that constant errors are eliminated. The consistent cutting of a disproportionate amount of softer or harder material of difficult richness within the same sample will introduce constant errors that no amount of averaging will eliminate, as will the jarring down into the sample of rich dust from other parts of the face. These

are the disadvantages against which the moil-sample has to contend, but my experience has proved to my satisfaction that they can be successfully overcome by men of skill and patience without increasing the size of the sample. This is merely saying that moil-sampling is work of the head rather than the arm. Moil-samples can be cut evenly and accurately by one who knows his work. The employment of chalk-lines to delineate the sample, the use of plenty of sharp moils, and bagging the sample and starting a new one wherever a change of rock-structure occurs, will do much to eliminate this error. Similarly, a thorough scrubbing down of the face prior to sampling, and catching the cuttings in a small ordinary meat pan held close to the moil under a good light, will practically eliminate the danger of extraneous material falling into the sample.

(3) They must be detailed and specific. On these points the honors are all with the moil-sample. Well kept notes show the exact location of the sample for future inspection and re-sampling if necessary, as well as its exact length; details of the geological structure, any faults or shear zones, the amount and kind of rock inclusions, the character of the hanging and foot-wall, and many other details, according to the peculiarities of the mine being examined. It should be noted that the width sampled is an important item, as averages are based on a product on which any error in measuring the width has as great an effect as an error in the assay. All these details render possible the making of an accurate, detailed, and specific map of the property. Structure can be sketched in and correlated, and ore-shoots colored. Then, when the final analysis comes, when the interpretation of the problem arises, the engineer can have all the collected facts laid before him on a single plan with an accuracy, detailed and correlated, impossible with a more massive method of sampling.

This little exposition of my views would not be complete without touching upon two of the most troublesome phases of moil-sampling, namely, high assays, and the much abused sampling-factor. A complete argument on high assays would require a treatise, and I must content myself with a mere statement of the results of my experience. I believe that high assays, except in extremely rare cases, are best left alone. The theory of averages does not permit the removal of a high result. Re-sample in the same channel, by all means; but if the result is confirmed, do not reduce. If a very rich spot has occurred once, it will occur again in just the proportion indicated by your samples, provided one has enough to give the law of averages a chance. There is just one warning: see how much the few erratic assays affect the result, and as you have so shrewdly observed in your editorial, there cannot be many of them, otherwise they are not erratic. If, say, two or three samples change unpayable ore to payable, it is not correct to let matters rest, as it would in effect amount to making a decision on those two or three samples; but one cannot remove them any more than leave them in: it is neces-

sary to obtain more information. Regarding the sampling factor, I should like to throw out two suggestions for argument. I have known men to sample a vein with widths running all the way from 6 in. to 6 ft., and because the average width was greater than a stoping width, let the result alone. The experienced man knows that every sample must be taken over a stoping width, or must be diluted with enough waste to make it so. The effect of such an error by a thoughtless or untrained man is to increase the tonnage and decrease the grade. The second and greater pitfall is in making insufficient allowance for rock that will come in from the hanging or foot-wall. Some men do not realize the difference between a machine-drill and a moil, or perhaps I should say a machine-drill and a ruling-pen. The result is a map that cannot possibly be substantiated in mining, and the principle of moil-sampling gets the blame. A careful study of the character of the hanging and foot-wall will often show that there is no way of avoiding the breaking of a tremendous proportion of waste. If this is included in the grade and tonnage, and then partly eliminated in the treatment-calculations, the results will be much more nearly those subsequently obtained in operating. I believe the sampling factor is largely due to this error of including insufficient waste.

As long as expense is an item in mining, moil-sampling will be the great resource in examining prospects and small mines. The number of examinations made in this way is tremendous, and they are not always made by competent men. On the other hand, a mill-test is a rather elaborate affair and comparatively few of them are made. The man in charge is more likely to be carefully selected for the work. When a fiasco based on moil-sampling occurs, sight is lost of these facts, and because the absolute number of failures by moil-sampling is greater, the proportion of mistakes by the two methods is not looked into. As a result, the reliability of moil-sampling is questioned. There is, however, one part of the work where the mill-test comes into its own. After the moil-sampling has been completed and the results correlated, if there are available statistics from mill-tests or past operation, by comparing these with the results from moil-sampling for the same part of the mine much valuable information may be obtained as to exact mining and treatment-conditions and the sampling factor, if any. More accurate conclusions can then be drawn as to how nearly the moil-samples in the rest of the explored territory indicate what will be obtained by mining. This is the true function of the mill-test; it is purely corroborative. That mine valuation is not an exact science, and that there are many pitfalls to be avoided, I heartily agree. Nevertheless, I maintain that the best conclusions of the value of any deposit that can be obtained are based upon moil-samples, skilfully taken, and competently interpreted, by men of sound training and experience.

The Extra-Lateral Right

The Editor:

Sir—When we are considering the extra-lateral right feature of the mining law with reference to a proposed new law, Mr. Colby's estimate (in your issue of June 2) of the amount of mining litigation chargeable to the apex-law is not a fair representation of the subject. For the purpose of intelligent discussion of this matter it is equally to the point to consider the vast array of indirect costs. The few big cases which reach the reports of the higher courts are only the spot-light performances of the great tragedy. The host of cases which are not appealed to the courts mentioned are only the beginning of the additional charges which must be considered. We must count the cases filed in the courts which, after great expense in development work and professional reports, are settled by compromise. We must count the cases on which, after much expensive and useless underground exploration and map-making and professional work, both legal and engineering, and arbitration costs, settlements are made without even a court-filing. Further, and saddest of all, take the case of the miner drawn into a controversy over extra-lateral rights who finds that the expense of driving in barren portions of his vein, necessary to prove his case, together with the court, engineering, and legal expenses, is so far beyond his means that he simply succumbs to polite robbery. The success of his rival may be due either to superior financial means or to a more advantageous physical situation. The case may be one in which the apex claimant is in the right, or it may be that of a covetous neighbor with plenty of means, hunting up a geological condition that will enable him to go after something previously found by another beneath the surface. Further, the cost of securing the vast array of lode-claims which are located (without any legitimate discovery) and patented to 'protect' real mines from apex-hunters and the like must be charged to the extra-lateral law.

Senator Thomas is quoted as representing that the multitude of cases of mining litigation arise from surface contests. Quite true; but the cause of those contests is traceable directly to the apex-law. Without that feature of the law, and its accompanying feature of pre-discovery, there would never occur the exasperating criss-crossing of mineral claims which causes the surface-litigation cases.

It is not the strict term 'litigation,' but the broader use, covering all of its expenses, direct and indirect, which is really in our minds when we discuss this subject in its bearing on the possible revision of the mining law. With this view I think Dr. Raymond's 99.9% is nearer the mark than Mr. Colby's 2%.

The law of the apex is upheld as a stimulus to the prospector. It was so intended, but the law of 1872 giving to mineral claims "all other lodes the apex of which are within the surface boundaries" is an iniquitous feature which is anything but an encouragement to the true discoverer; in fact, with the unnecessary surface allow-

ance of 600 ft. it offers greater encouragement to the land grabber as against the prospector.

Mr. Colby's eleven "summarized statements" I consider generally well chosen and acceptable, but I must take exception to numbers 7 and 10.

In the case of No. 7 the extra-lateral right feature does not apply; it is only the application of the antecedent discovery requirement which gives the advantage to the agricultural claimant, and to prevent this it is true that the logic of the situation leads to the necessity of separating surface and mineral titles. See below under No. 9.

No. 10 is a bugbear regularly brought forward by those who would retain the apex-law. To begin with, the supposed confusion over the application of a new law at most only applies to old mining districts, and even there it seems to me to be a false alarm. Rights already acquired cannot be affected and the means of defending them can never be worse than now. A new-law mining claim without extra-lateral rights located in a nest of old-law claims would secure only what the older locations had not already acquired. Everyone would understand that. The new locator could not in any sense threaten his older neighbors. The operation of a law eliminating extra-lateral and antecedent discovery features would be to lessen litigation in old districts while preventing it in the new.

No. 9 is a statement with which I fully concur and which I regard as the most important fact to keep in mind in any discussion of this subject. Indeed in the number of the cases of disputed titles and the incompatibility with physical conditions the antecedent discovery feature is worse than the apex-law. And further it is the antecedent discovery feature, or the abuse of it by presumption, that is used in all sorts of right-of-way, timber, water, and building-site frauds. My views on this matter have been given in the discussion on the article by E. D. Gardner on the antecedent discovery requirement (Bulletin 120, A. I. M. E., December, 1916, p. 2202). In brief, I regard the complete divorce of surface and mineral titles as the only logical solution of the mining-law problem.

Shift Bosses, Good and Bad

The Editor:

Sir—During 1915 I was employed by an Idaho mining company as miner. Aside from the necessity of earning a living, I had 'rustled' that particular mine to gain a practical knowledge of methods employed. At this property one is apt to be impressed by the general efficiency so much in evidence, and were I one of the stockholders making a visit, I might congratulate the management while I spent my monthly dividends, and think there was no room for improvement. To the miner, however, the case is different. The 'Moguls' we miners worried about were the shift-bosses, and as our aptitude for the day's work was usually influenced by the 'shifters' I know the stockholders often got the worst of the deal. The im-

pression is general that any thorough miner makes a competent shift-boss. Having worked under three shift-bosses in that mine, I found the ideas as to what constituted a fair day's work to vary so that I thought the situation worth studying, particularly as the characters of the men varied but little. From my deductions I believe a large proportion of the trouble between capital and the man who piles it up could be avoided by a little more intelligent attention in the selection of subordinates by superintendents. As an illustration, I shall name two shift-foremen Page and Sage. Both of these men were first-class miners, and to their superiors they were good fellows, each doing his best in the interest of his employers, as his judgment dictated. As the shift starts work, Page and Sage go through the stopes on their respective levels. Page seeks an opportunity to dig into the men and speed them up; he always finds a number of cases, due often to many little causes not necessarily the miners' fault. In this case, the miner or mucker gets a grouch that is increased by this fault-finding, and he doesn't give a 'whoop in Hades' whether his holes break or not, just so he gets a showing; if mucking, he's apt to throw good ore in the gob and as much waste as he dares down the ore-shoot; he wastes powder and time; handles tools carelessly; doesn't cover the stope floor before shooting; leaves machines and tools exposed to flying rock, and the like, and thinks he's getting even with the whole works. On the other hand, Sage forgets that his night's sleep may have been spoiled or that his digestion is bad, and makes his round with a cheery word for each man. He may not remember Bill from Mike, but he's looking for trouble, not to raise Hell about it, but to give a hand if need be, or a word of advice, and the result is that he starts the day right for each man. They know they can ask advice from Sage, but they will not risk Page's displeasure by doing so. Sage realizes that in these mad days you must make miners of any promising material, and draws from his fund of experience. Page expects miners to be ready-made, and hoards his experience, because he believes he will lose prestige by acting human. Page is always going the rounds of the stopes watching the men and 'digging in.' Sage puts in most of his time with the green men, and as he's sincere in his desire to teach, it is seldom resented; he knows at the end of a shift whether a man has done a reasonable and profitable day's work, and he makes allowances for unusual conditions; the men feel that they are trusted as men, and not driven as mules, and the company benefits accordingly. But Page never has a word of praise for creditable work. Sage has, but he does not make the mistake of piling it on too thick, and he doesn't play favorites, and he divides bad or wet places as equally as possible. One tells of the faithful and intelligent work that his men do, while another writes that his men will not do more than they positively have to in order to hold their jobs. What's wrong? A man like Page adds fuel to the flames of class hatred and discontent, and the sooner he's found out and sent back to a job timbering or mining, the better.

MINER.

Replacement of Sulphides by Quartz

By H. N. WOLCOTT

*Among the many cases of replacement of one mineral by another, that of quartz or silicates by pyrite, or even other sulphides is not uncommon, but the reverse of this process does not appear to have been recorded. The case described therefore seemed worthy of record. The specimens were obtained from the Old Town mine, in Russell gulch, Idaho Springs, Colorado. In the rough, they appeared to consist largely of chalcopyrite, with grains of tetrahedrite. The polished surface of some of the lumps, however, showed numerous rounded grains of pyrite, and minute fractures. These smooth surfaces studied by reflected light under the microscope exhibited interesting relationships. It was seen that while chalcopyrite and tetrahedrite were probably contemporaneous, numerous grains and rosettes of pyrite, of varying size were scattered through the chalcopyrite. A few were seen in the tetrahedrite. As the pyrite is completely surrounded by the chalcopyrite (and also the tetrahedrite) it may be of earlier age. The pyrite rosettes and grains consist in some instances entirely of that mineral. In other cases, by far the most numerous, the rosettes show an irregular central mass of quartz and often connecting with the exterior by one or more veinlets of quartz. Some show a little quartz on the outside of the pyrite grain, and in one case the quartz surrounding the pyrite showed the crystal outlines of quartz. The quartz, in addition to its occurrence in the pyrite grains, fills numerous narrow fractures in the chalcopyrite and tetrahedrite; indeed in some parts of the specimen, the chalcopyrite and tetrahedrite have been crushed to a mass of angular fragments with quartz filling the crevices. The quartz veinlets passing through the chalcopyrite and tetrahedrite are usually clean cut, and form connecting lines between the quartz in the pyrite rosettes. In places, however, the quartz veins enlarge and project into the chalcopyrite and tetrahedrite in such an irregular way as to suggest replacement. Some of the areas in the tetrahedrite might be regarded as contemporaneous with the sulphide were it not for their connection with the feeding channels. Following the deposition of the sulphides, fracturing of the ore occurred, resulting in the introduction of silica that was deposited in the chalcopyrite and tetrahedrite largely as fillings of fractures, but in the chalcopyrite at least in part by replacement. In addition it was deposited in the pyrite almost wholly by replacement.

REGULATION of freights, as carried out by the British Government, extends to the fixing of preference-cargoes, and this is done in all ports of the world. For example, administrative orders have selected certain products from Bolivia as being more urgently needed than tin, in consequence of which tin is moving forward at an extremely slow rate. The ocean freight rate quoted on

Bolivian tin concentrate to England is nominally £10 per ton, and insurance is 3.3%. The Bolivian Government is alarmed over the situation, fearing a virtual collapse of the tin-mining industry, which would strike a severe financial blow at the prosperity of the Republic.

Preparation of Pure Molybdenum

A paper presented by C. H. Humphries, of the Commercial Research Co., Long Island City, New York, on Molybdenum, at a recent meeting of the New York section of the American Institute of Mining Engineers, was devoted chiefly to the preparation of pure grades of molybdenum. He reviewed briefly the geology of molybdenum ores and showed samples of molybdenite and wulfenite. Molybdenite, MoS_2 , is the principal source of metallic molybdenum. It is reduced by carbon in an electric furnace. The ordinary methods, however, produce a metal which contains some carbide, and in order to obtain pure molybdenum the trioxide or the ammonium molybdate has generally been used, as the starting point. The molybdate is made from the sulphide, and this is reduced in an atmosphere of hydrogen in an electric furnace, producing a crystalline material which passes through several stages of purification. The process is analogous to the well known General Electric tungsten-reduction process. This crystalline product is placed in a nickel or nickel-plated boat in a gas-furnace and heated to 900° to 1000°C . It is then crushed and screened, and reduced again for several hours at 1200°C . It is then examined for oxide by inspection. It appears streaky if oxide is present. If a blue tint is observed on shaking in water, oxide is present. It would be desirable to reduce finally at about 1400°C ., but there is danger of the material becoming contaminated with iron if a nickel-plated iron boat is used. It is desirable to have less than 0.01% of iron if molybdenum wire is to be made. After the final reduction the metal is powdered, then pressed in a steel mold, and heated in an electric furnace for about a half hour at 1200 – 1300°C . The metal sinters and becomes hard, but is not yet suitable for working. It is then placed in a furnace, the air displaced, and a current of about 100 amp. passed through the metal. It shrinks and forms a true molybdenum rod. It is then swaged and made into smaller rods, wire, foil, and other forms. The swageing is done hot from the electric-furnace at about 1400°C . The metal runs through dies of high-speed steel down to 0.001 in., the smallest size for practical purposes being 0.005 to 0.01 in. If the pure metal is heated to 1200°C . several times and quenched the surface can be made glass-hard. Some molybdenite contains calcium and barium, and these are hard to keep out of the metal. They prevent working of the metal even when less than 0.1% is present.

Molybdenum was proposed as a substitute for platinum in jewelry. It is just as beautiful, and is permanent, and can be produced at present for 25c. per gramme.

Saline Valley Tramway

By F. C. CARSTARPHEN

*Saline valley is situated in Inyo county, California, about 20 miles north-east of Owens lake. It is separated by the Inyo mountains from the Southern Pacific railroad running through Owens valley. The valley has no outlet, but there are several large springs and a constant flow of water in Hunter canyon. There is a large deposit of salt covering about 1500 acres of the floor of the valley. The existence of this salt deposit has been known for some time, but lack of transportation facilities prevented its commercial development. Topographic conditions render the economical construction of a railroad into the valley impracticable. A pipe-line across the Inyo mountains by which brine could be pumped to evaporating-vats near the railroad in Owens valley was also considered, but this plan was abandoned. While it was found feasible as a means for transporting the brine, it did not provide for bringing in supplies needed by the operations incidental to collecting the salt and pumping. Accordingly an aerial tramway was given the preference. After the surveys were completed, a contract was let by the Saline Valley Salt Co. to the Trenton Iron Co., a subsidiary of the American Steel & Wire Co., for the construction of a Trenton-Bleichert tramway. It was designed to carry salt weighing 60 lb. per cu. ft., the slope-length being 69,645 ft., the capacity, 20 tons per hour, the elevation of the discharge-terminal above the loading-terminal, 2450 ft., the carriers to have a volume of 12 cu. ft., and the speed of the traction-rope to be 500 ft. per minute. This required a spacing of 525 ft., or an interval of 63 seconds between carriers. About 112 hp. is required for the operation of the tramway. The principal equipment exclusive of structures and operating machinery is as follows:

1½-in. steel track-cable, feet	13,850
1½-in. steel track-cable, feet	55,450
¾-in. steel track-cable, feet	69,300
¾-in. steel traction-rope, feet	141,000
Steel buckets	286
Track-cable saddles	240
Steel traction-rope rollers	240

From the loading-station at the edge of the salt-field, which has an elevation of 1060 ft., the tramway runs south along the mesa for 2½ miles to the eastern foot of the mountains, at an elevation of 1800 ft. From that point the ascent is rapid to the control station No. 1, where an elevation of 3720 ft. is attained. This part of the line is known as Section I. At station No. 1 there is a horizontal angle of 35°30'. Section II extends to control station No. 2, which has an elevation of 6100 ft.

Section III extends to control-station No. 3 at the summit, where there is a horizontal angle of 2°28'. Section IV extends to control-station No. 4, which has an eleva-

MAP OF SALINE VALLEY AND THE TRAMWAY

tion of 6330 ft. At this point there is a horizontal angle of 10°48'. Section V extends to the discharge-terminal on the narrow-gauge line of the Southern Pacific railroad. The elevation is 3625 feet.

PROFILE OF LINE

*Abstract: Proc. Am. Soc. Civil Eng., by F. C. Carstarphen, tramway engineer, American Steel & Wire Co., Trento, New Jersey.

For transporting material on the western slope of the mountains, it was possible, by making use of an old road and extending it, to construct a wagon-road to the summit, the total distance from the valley being 10 miles. At one point on this road there was a stretch of 300 ft. with a grade of 25%, and this grade could not be eliminated or reduced except at prohibitive cost. This became the ruling grade for hauling material between control stations 4 and 1, and limited the maximum load for eight-horse teams to 5000 lb., heavier loads requiring 10 or 12 horses. A camp was established $3\frac{1}{2}$ miles west of the summit. Teams made one round trip per day between the railroad and the camp. Those quartered at the camp hauled the wagons from that point to the summit, where the material was unloaded, three round trips being made in two days. For every 100 tons of construction material hauled from the railroad to the camp, 1.5 tons of grain, 7.7 tons of hay, and 33 tons of water had to be transported. The cost of maintaining a team consisting of eight horses and a driver was \$15 per day at the railroad. On account of hauling feed and water from the railroad, the cost of a team at the camp was \$21 per day. Construction of roads on the eastern slope of the Inyo mountains was found impracticable, although a trail was constructed from the summit to Saline valley. Since a large part of the machinery was too heavy to be moved by pack-animals, temporary double-cable reversible tramways were constructed for transporting material for the structures on Sections I and II. The diameter of the track-cables used was $\frac{3}{4}$ in. and of the traction-rope, $\frac{3}{8}$ in. The cost of transporting this equipment from the end of the wagon-road at the summit was as follows: 600 tons of material was moved 8300 ft. at a cost of \$4.20 per ton; 375 tons 2600 ft. farther at a cost of \$2; 260 tons 4000 ft. farther at \$3.50; and 210 tons 2700 ft. farther at a cost of \$2.90 per ton.

The cost per day for the crew to operate, load, and unload these temporary cableways was from \$35 to \$42. The capacity in tons per day, while operating, ranged from 13.3 to 33.3 tons. Allowing for the time required for constructing, taking down, and moving, the capacity ranged from 6.3 to 19.3 tons. The material for control-station No. 1 was carried on a temporary cableway from the floor of Saline valley. A wagon-road runs from Big Pine on the railroad, 55 miles to the floor of Saline valley. About 375 tons of material was hauled over this road at a cost of \$35 per ton. Some of the other material was moved from the summit down Daisy canyon on a sort of sled. The cables between the summit and control-station No. 2 were strung by letting them down the mountain-side by gravity. From three to five men were required at the lead-end to put the cables on the traction-rope guide-sheaves at the towers and stations. Wooden blocks 4 by 8 in., bolted together, were used as brakes to control the velocity of the cables. From the floor of Saline valley to control-station No. 1 the cables were handled with a winch driven by a gasoline-engine. On Sections IV and V the cables were strung and placed under tension in the usual manner, except that on Sec-

tion V the grade was sufficient to make it desirable to use the gravity method. In placing the traction-rope for Sections II and III, it was threaded around the grip-sheave at the summit station. The grip-sheave acted as a driving-sheave, because of the use of a brake on the reel, which imposed tension in the traction-rope before it passed around the grip-sheave. The traction-rope was also passed through hauling-clamps before reaching the grip-sheave, in order to hold it when splices were being made, or in cases of emergency. After bringing the traction-rope for one side to control-station No. 1, the upper end at the summit was snubbed and the rope for the opposite side was let down in the same manner. After the upper ends had been spliced, the ropes were cut at control-station No. 2 and passed around the tension and grip-sheaves of this station.

The towers and structures are carried on concrete foundations, the water required for making the concrete being hauled in tanks or packed by mules for distances ranging from 1 to 7 miles. This was also necessary for the water required for the camps, except those at the railroad, in Daisy canyon, and at Saline valley.

The tramway was completed and the first bucket of salt hauled on July 2, 1913, power being obtained from the Los Angeles aqueduct. The line worked satisfactorily when the buckets were loaded about two-thirds full. When efforts were made to carry full buckets, it was found that the number of accidents resulting from carriers slipping on the traction-rope was excessive. An investigation showed that while the tramway had been designed to carry air-dried salt, which weighs 60 lb. per cu. ft., the average weight of the wet salt was 80 lb. per cu. ft. It was also noted that while buckets loaded with dry salt were carried without difficulty, when wet salt was being transported, a few of the buckets would slip on the traction-rope, particularly on the steeper parts of the tramway. With the exception of the first $2\frac{1}{2}$ miles on the floor of Saline valley, the cables throughout almost the entire line had a slope exceeding 30%, and in some cases this slope exceeded 85%.

The principal departure from standard tramway-practice was the division of the distance between the loading-terminal and the summit into three sections, and the distance between the summit and the discharge terminal into two sections. Experience has shown that it is not economical to attempt to use traction-ropes of large diameter. The total stress developed in such ropes when lifting 20 tons of material through a vertical distance of $1\frac{1}{2}$ miles at a rate of 500 ft. per minute is too great to permit the use of a single rope. Multiple traction-ropes, arranged in parallel, are not satisfactory. Accordingly, the tramway was constructed in sections so as to permit the use of a traction-rope of moderate diameter. The stations were arranged so that there would be a constant difference in their successive elevations, giving essentially the same stress on the traction-rope of each section. These stresses, however, are not absolutely constant, because the friction developed by the moving carriages varies with the length of the different sections. Ex-

perience has shown that, irrespective of the constancy of tension in two traction-ropes in service, they do not maintain precisely the same diameter. Consequently, friction-grips that will hold satisfactorily on the larger of

BUCKET LEAVING LOADING-TERMINAL

the ropes are likely to slip on the smaller one. For this reason the Webber grip was not used. The Pohlig screen-grip was also rejected because of the acceleration required to close the gripping-lever, which moves in a plane

BUCKET OF SALT AT LOADING-TERMINAL

parallel with the direction of motion; also because of the difficulty of maintaining a proper limit for the throw of the closing-lever when operating on ropes of different diameters, so as to engage the detacher properly instead of under-running it. The overhead Bleichert-grip was

rejected because the tension of the traction-rope in passing through the structures on the crests tended to overturn the carriers, especially those on the empty side. The under-hung Bleichert-grip was rejected because it is operated by the weight of the load acting on the movable jaw, and it was feared that on the steeper grades this would not be sufficient to keep the carriers from slipping on the rope. This type of grip and carriers is also expensive as compared with others. This is an important consideration in view of that fact that 286 carriers were required. A special grip of the under-hung, top-opening, trunnion type was therefore designed. These grips were used on the line for some time, but were not satisfactory, slipping occasionally on the extreme slopes, because of the variation in the weight of the salt.

SALINE VALLEY FROM POINT NEAR SUMMIT

Finally the American Steel & Wire Co. took over the operation of the line in order to determine what defects existed and what replacements should be made. As a result of this investigation, a new grip, the Universal Wico, was designed, and it has been used from that time with satisfactory results. This grip requires a force of about 40 lb. on the closing-lever to fasten it. It will hold a carrier loaded with wet salt on the steepest grades. A special lubricating-system is attached to the carriers to provide an adequate supply of oil for the wheels and pins.

Sections III and IV are controlled from the summit, both driving-sheaves being mounted on the same shaft. The power developed by the descending loads on Section IV assists in raising those on Section III. As the carriers on Sections I, II, and III are being lifted, there is a possibility of the line reversing its direction of motion, on account of the unbalanced weight of the carriers on the two sides. Accordingly, each of the stations is equipped with a reverse-preventer. This consists of a large circular plate fitted with shoes containing ball-races, which are under the control of a centrifugal governor. When the governor is up to speed, the balls are restrained so that the plates run freely. When the line

stops the balls immediately nip the plate, and a reversal of motion is prevented. The drives at the stations are similar in design, except that, as already mentioned, the two sheaves at the summit are mounted on the same shaft. The drives consist of an 8-ft. grip-sheave bolted to a brake-run 7 ft. 2 in. diam., with a 12-in. face, and this, in turn, carries an 8-ft. spur-gear. The latter is driven by an 18-in. pinion mounted on a shaft fitted with a friction-clutch belted to a 75-hp. Allis-Chalmers, 3-phase, 2200-volt, induction motor. On Section V, this motor acts as a dynamo-brake instead of serving as a driver.

latch to prevent their being blown open by the high winds that frequently occur. The control-stations are equipped with telephones and the line-riders also carry telephones, which may be attached to the line at any point, in addition to which there is a bell-signal system. The electrical transmission-line is of the usual pole-construction, carrying copper wires for a 3-phase circuit. The transformer-stations are of the out-door type. The line-voltage is 33,000, which is stepped down to 2200 for use in the motors of the driving stations. The crew consists of two men each at the loading and discharge-stations

and at the four control-stations on the line. There are also four line-riders and a foreman who has general supervision of the entire line. The tramway carries 23 to 24 tons of salt per hour at a cost for labor and power of 4.6c. per ton-mile. The line is not designed for passenger-service, but the line-riders use it in preference to following the rough trails on horseback.

Several methods of gathering the salt have been tried with varying success. At present the plan is to flood the salt-field with water piped from the springs. The fresh water dissolves the salt rapidly. If the supply of fresh water is then stopped, evaporation caused by the summer sun is excessive, and pure salt-crystals gather in the brine, resembling flat plates that are easily shoveled into conical piles about 2 ft. high and 3½ ft. in diameter at the base. Each pile is assumed to contain from 400 to 500 lb. The piles are arranged in rows approximately 12 ft. apart, the spacing between the piles being 6 ft. Mexican labor is found to be most satisfactory in gathering salt. Each man piles from 8 to 10 tons per day.

Theoretically, the salt remains in piles until the brine has drained. As the mother liquor contains most of the impurities which might contaminate the salt, this step is an additional insurance of its purity. However, the salt does not drain freely, but remains damp for a considerable time. When the salt is gathered, a buggy of a special type is used, made of galvanized iron and having a body with a channel-like cross-section. Since the ground is soft, the rear wheels are 20 in. diam. and have a 12-in. face. The front wheels are 16 in. diam. and have a 4½-in. face. The bed is 3 ft. wide, 8 ft. long, and 6 in. deep. The axles are attached rigidly to the body, so that curves are turned by slipping the front wheels. These buggies carry from 500 to 1000 lb. of salt, and are hauled across the field by a ¾-in. cable operated by a gasoline-engine. At the dumping-point the buggies are pulled up an incline plane until they assume an angle of approximately 44°, at which slope the wet salt slides freely into

The grip-sheaves carry a special rim, in which there are 96 pairs of toggle-jaws. The jaws are held open by gravity or by a special flat spring. When the traction-rope passes around the sheave, the pressure developed on the bottom of the-groove on the jaws is sufficient to cause them to close and grip the rope tightly. This increases the friction between the sheave and the traction-rope, augmenting the efficiency. The brakes are of the compound-differential type, and are actuated by hand-wheels and screws. This ensures their being applied gradually, so that the line may not be wrecked by sudden stoppage, as might be the case with brakes operated by a solenoid.

The hangers on the carriers are made longer than in standard practice, so as to provide clearance between the traction-rope guide-rollers used in the rail-structures on the ridges that run transversely to the line of the tramway. The buckets are covered to prevent dust from reaching the salt. The covers are provided with a special

a hopper above a car which has a body 30 in. wide, 4 ft. 6 in. long, and approximately 30 in. high. The bottom of this car is hopped both ways at an angle of 45° , so that the sides, instead of the ends, are used for doors. These cars are operated on a double-track railway, about $\frac{1}{2}$ mile long, by an endless-rope haulage-system operated at a speed of 200 ft. per min. A 10-hp. gasoline-engine moves seven loaded and seven empty cars on these tracks. The cars dump into a boot serving a drag-conveyor, which elevates the salt to a point high enough to command the 50-ton bins at the loading-terminal. Here the tramway-buckets are filled by a lever-chute of the ordinary type. The buckets are dispatched from the loading-terminal at the top of an automatic gong. The rate established is 56 buckets per hour.

White Smith was president, W. H. Leffingwell, chief engineer, Daniel Kuhnle, superintendent, M. O. Bolser, electrical engineer, and Harry Hilderman, foreman of construction for the Saline Valley Salt Co. Among the engineers of the Trenton Iron Co. and the American Steel & Wire Co. who took part in the construction of the tramway were S. S. Webber, F. C. Carstarphen, William Hewitt, C. H. Wickham, L. T. Hays, T. J. Murphy, R. H. Hall, and George Hall.

Graphite

A market for graphite exists among manufacturers of graphite crucibles, pencils, and lubricants. Perhaps the largest single use of graphite is in lubrication. The ideal form for lubricating purposes is the exceedingly thin flake-graphite, that coming from the Ticonderoga district in New York State being the standard of reference in this country for thinness of flake and for purity. The amorphous variety of graphite is objectionable for this purpose on account of its tendency to cake in the gearing. For the making of crucibles graphite should have a thick body, and should possess the characteristic known in the trade as 'sharp,' which implies a well-defined shape, lustrous, and free from a tendency to break down into smaller scales and non-lustrous powder. The best material for crucibles was formerly obtained from the mines in Ceylon, but in recent years large shipments of suitable graphite have been made from the deposits in Madagascar. Pencil-graphite contains chiefly the amorphous variety, with enough of the flaky sort to impart smoothness. Formerly Bavaria and Siberia supplied the larger proportion of the pencil-graphite used in this country, but today practically our entire demand is met by the output of the Mexican mines, a small quantity also coming from Korea. The physical properties of graphite control its application and its consequent value to the manufacturers more than its chemical composition. Accordingly graphite is universally sold on sample. Local assayers do not possess the equipment for making the necessary physical tests, and as the adaptability of graphite is a matter developed in the art of manufacture it is difficult to express the desirable qualities in such scientific terms as would not be open to

misinterpretation in the hands of men inexperienced in this special industry. On satisfactory evidence that a sample accurately represents amounts available in excess of carload lots the large manufacturers, such as the Joseph Dixon Crucible Co., the Franco American Chemical Co., Inc., R. M. Hollingshead Co., U. S. Graphite Mills, and Whitaker & Co., will test a sample submitted to them, and will quote the true market price in accordance with the estimates their experts make as to its peculiar fitness for their needs. Amorphous graphite is not amenable to froth-flotation, but the lustrous flake-graphite usually yields a concentrate by that process.

Metallurgists Needed by the Government

The United States Civil Service Commission announces competitive examinations for metallurgists as follows: A vacancy in the Springfield Armory, Ordnance Department at Large, Springfield, Massachusetts, at \$3000 per year, and future vacancies requiring similar qualifications, at the Springfield Armory or elsewhere, will be filled from this examination. The duties of this position consist in the superintendence of the acceptance-tests of steel and oil, and of the heat treatment of dies and tools. The applicant should have had experience in the chemical analysis and the photomicrographical examination of steel, and in the prescription and supervision of the heat-treatment of tools. A vacancy in the department of ordnance, navy yard, Washington, D. C., at \$2000 per year, and future vacancies requiring similar qualifications throughout the United States will be filled from this examination. The duties of this position will be the laboratory control of the melting operations in the manufacture of open-hearth, converter, and electric-steel castings and ingots; non-ferrous mixtures; the heat-treatment of forging and casting of both alloy and carbon-steels; the interpretations of physical and chemical tests, and their application to shop operations. Until further notice and on account of the urgent needs of the service, applications will be received at any time, and the papers will be rated immediately upon their receipt, in order that appointments may be made with the least possible delay.

ZINC-OXIDE is made by mixing the raw crushed ore with fine anthracite, and charging it into furnaces built on the plan of a fire-box, provided with an under-grate blast of air. The furnace-chamber is closed by a door. The furnaces are placed back to back, and each block of furnaces discharges the fume into sheet-iron flues which convey it to the collecting system, under draft from a suction-fan. The collection is accomplished in a bag-house. The oxidized ores are necessary for this process. Zinc-blende must be roasted previously. Any lead present in the blende re-appears in the final product as lead sulphate. Leaded oxides are graded according to color and content of lead sulphate, ranging from 5 to 30% of that compound.

The Empirical Formula in Milling Control

By A. J. SALE

The formula for calculating the ratio of concentration and percentage of extraction from assays of the heads, tailing, and concentrate, without having the corresponding weights, is called the empirical formula. This is really a misnomer, since the formula, being based entirely upon theory and not experiment, is in reality the reverse of empiric. Engineers know how this formula is derived, but few have made sufficient study of it to enable them to state to what extent it may be trusted, that is, fully to understand what effect errors of sampling and assaying will have upon the results.

The derivation of the formula is as follows: Let H = assay of heads; T = assay of tailing; C = assay of concentrate, assays being in ounces for gold and silver, and in percentages for copper, lead, and other metals. Also let R = ratio of concentration; E = extraction, the extraction being a decimal fraction which must be multiplied by 100 to give the percentage. Assume that one ton of heads will make X ton of concentrate, X being a fractional part of a ton. After the X ton of concentrate has been removed from the 1 ton of heads, there will remain $1 - X$ ton, which represents the weight of the tailing. Now the amount of metal in the 1 ton of heads is $1 \cdot H = H$. The amount of metal in the X ton of concentrate is XC , and the amount of metal in the tailing is $(1 - X)T$. But, since the amount of metal originally contained in the heads either goes into the concentrate or into the tailing, $H = XC + (1 - X)T = XC + T - XT$.

Therefore,

$$X(C - T) = (H - T)$$

Or

$$X = \frac{H - T}{C - T}$$

Now 1 ton of heads produces X ton of concentrate, therefore $\frac{1}{X}$ ton of heads will produce 1 ton of concentrate. Hence the ratio of concentration is

$$R = \frac{1}{X} = \frac{C - T}{H - T}$$

In verbal statement this formula expresses: The ratio of concentration equals the assay of the concentrate less the assay of the tailing, divided by the assay of the heads less the assay of the tailing.

Since the extraction is the ratio of the amount of metal saved in the concentrate to the amount originally contained in the heads,

$$E = \frac{XC}{H} \quad \text{But } X = \frac{H - T}{C - T}$$

$$\text{Hence } E = \frac{(H - T)C}{(C - T)H} \quad \text{But } R = \frac{C - T}{H - T}$$

$$\text{Therefore } E = \frac{C}{HR}$$

Expressed verbally this formula means: The extraction equals the assay of the concentrate divided by the product of the ratio of concentration and the assay of the heads.

This is a convenient formula where a good slide-rule is handy, but personally I prefer one which is entirely by division, without awkward figures. To obtain such a formula: Let A = the apparent extraction, or $\frac{H - T}{H}$.

$$\text{Now, } E = \frac{C}{HR} = \frac{(C - T) + T}{HR} = \frac{C - T}{HR} + \frac{T}{HR} = \frac{(C - T)(H - T)}{(H - T)HR} + \frac{H - (H + T)}{HR}$$

$$\text{But } \frac{C - T}{H - T} = R$$

$$\text{Therefore } E = \frac{R(H - T)}{HR} + \frac{H - (H + T)}{HR} = \frac{(H - T)}{(H)} + \frac{1 - \frac{(H + T)}{H}}{R}$$

$$\text{But } \frac{H - T}{H} = A$$

$$\text{Hence } E = A + \frac{1 - A}{R}$$

Expressed as a percentage, this formula is: $100 A - \frac{100 - 100A}{R}$ = per cent of extraction.

This is the most easily operated of any extraction formula; to use it, subtract the assay of the tailing from the assay of the heads, and divide by the assay of the heads; multiply the result by 100 to express the percentage. Take the difference between this percentage and 100 and divide it by the ratio of concentration; add the quotient to the first percentage and the result will be the percentage of extraction.

Having derived satisfactory formulae, next determine the effect of errors in H , T , and C . This is best done by applying one of the first principles of calculus. Since there is a probability of error in H , T , and C at the same time, it will be necessary to assume that all of them are variables.

$$\text{Take the equation } R = \frac{C - T}{H - T}$$

Differentiating and simplifying, we find $d, R =$

$$-\frac{(C - T)}{(H - T)^2} \cdot d, H + \frac{(C - H)}{(H - T)^2} \cdot d, T + \frac{1}{(H - T)} \cdot d, C = -\left[\frac{(C - T)}{(H - T)^2} \cdot d, H - \frac{(C - H)}{(H - T)^2} \cdot d, T - \frac{1}{(H - T)} \cdot d, C\right]$$

$$\text{Also take the equation } E = \frac{(H - T)C}{(C - T)H}$$

Differentiating and simplifying, we find

$$d, E = + \frac{CT}{(C - T)H^2} \cdot d, H - \frac{C(C - H)}{H(C - T)^2} \cdot d, T - \frac{T(H - T)}{H(C - T)^2} \cdot d, C$$

In the above formulae, d, R equals the change in the ratio of concentration due to errors in sampling or assaying of heads, tailing, and concentrate; d, E equals the change in the extraction due to the same errors; d, H equals the actual error of H ; d, T equals the actual error of T ; d, C equals the actual error of C .

If we make $R' = R + d, R = R - \left[\frac{(C-T)}{(H-T)^2} \cdot d, H - \frac{(C-H)}{(H-T)^2} \cdot d, T - \frac{1}{(H-T)} \cdot d, C \right]$

and replace (d, H) , (d, T) , and (d, C) by actual values which are determined by experiment, one can then approach a true empirical formula which shows the limits to which the calculated ratio of concentration may be trusted.

In like manner, make $E' = E + d, E = E + \left[\frac{CT}{(C-T)H^2} \cdot d, H - \frac{C(C-H)}{H(C-T)^2} \cdot d, T - \frac{T(H-T)}{H(C-T)^2} \cdot d, C \right]$

For a practical application of this principle, assume that, in a flotation-mill operating on copper ore, there is made a series of duplicate samples of heads, tailing, and concentrate, under conditions as variable as possible in conformity with accuracy. If this work be properly performed, one is entitled to assume that the mean-assay represents the true values of H , T , and C . Then the variations between the originals and duplicates from the mean will represent the most probable errors, or (d, H) , (d, T) , and (d, C) .

Suppose that the assays be as follows:

	Original samples	Duplicate samples	Mean	Variation from mean
	%	%	%	%
H	2.00	2.40	2.20	0.20
T	0.25	0.15	0.20	0.05
C	10.70	9.70	10.20	0.50

From the above table it is seen that

$$\begin{aligned} H &= 2.20 = 0.022 \\ T &= 0.20 = 0.002 \\ C &= 10.20 = 0.102 \\ d, H &= 0.20 = 0.002 \\ d, T &= 0.05 = 0.0005 \\ d, C &= 0.50 = 0.005 \end{aligned}$$

The errors may be either + or -; and, for studying maximum probable errors the signs producing maximum variation must be selected. It is seen that in the formula

$$R' = R - \left[\frac{(C-T)}{(H-T)^2} \cdot d, H - \frac{(C-H)}{(H-T)^2} \cdot d, T - \frac{1}{(H-T)} \cdot d, C \right],$$

if d, H is taken at opposite sign from d, T and d, C , then R' will either become maximum or minimum according to whether d, T and d, C are taken as positive or negative. Also in the formula

$$E' = E + \left[\frac{CT}{(C-T)H^2} \cdot d, H - \frac{C(C-H)}{H(C-T)^2} \cdot d, T - \frac{T(H-T)}{H(C-T)^2} \cdot d, C \right]$$

if d, H be taken at opposite sign from d, T and d, C , then E will either become maximum or minimum according to whether d, T and d, C are taken as negative or positive.

To apply the results from the above table, assume that d, T and d, C are positive; this forces d, H to be negative, if extreme probable variations are to be shown.

For the tabulated figures:

$$R = \frac{C-T}{H-T} = \frac{(0.102-0.002)}{(0.022-0.002)} = \frac{0.100}{0.020} = 5$$

That is, five tons of ore will produce one ton of concentrate.

$$A = \frac{H-T}{H} = \frac{(0.022-0.002)}{0.022} = \frac{0.020}{0.022} = 0.909$$

$$E = A + \frac{1-A}{R} = 0.909 + \frac{0.091}{5} = 0.927$$

That is, the extraction is 92.7%.

$$d, R = - \frac{(C-T)}{(H-T)^2} \cdot d, H + \frac{(C-H)}{(H-T)^2} \cdot d, T + \frac{1}{(H-T)} \cdot d, C$$

$$d, C = - \frac{(0.102-0.002)}{(0.022-0.002)^2} \cdot (-0.002) + \frac{(0.102-0.022)}{(0.022-0.002)^2} \cdot (0.0005) + \frac{1}{(0.022-0.002)} \cdot (0.005) = \frac{1}{10} + \frac{1}{10} + \frac{1}{10} = 0.85$$

Now a complete change of signs for d, H , d, T , and d, C will give this same figure with opposite sign.

Therefore $R' = R + d, R = R \pm 0.85 = 5 \pm 0.85$, or the limits of the probable true ratio of concentration will vary between 5.85 and 4.15.

$$\begin{aligned} \text{Now } d, E &= + \frac{CT}{(C-T)H^2} \cdot d, H - \frac{C(C-H)}{H(C-T)^2} \cdot d, T - \frac{T(H-T)}{H(C-T)^2} \cdot d, C \\ &= \frac{(0.102)(0.002)}{(0.102-0.002)(0.022)^2} \cdot (-0.022) - \frac{(0.102)(0.102-0.022)}{(0.022)(0.102-0.002)^2} \cdot (0.0005) - \frac{(0.002)(0.022-0.002)}{(0.022)(0.102-0.002)^2} \cdot (0.005) \\ &= - \frac{1.02}{121} - \frac{0.204}{11} - \frac{0.01}{11} = -0.026 \end{aligned}$$

But a complete change of signs for d, H , d, T , and d, C will give this same figure with opposite sign. Therefore $E' = E + d, E = E \mp (0.026) = 0.927 \mp (0.026)$.

That is, the limits of the probable true extraction will vary from 0.901 to 0.953, or from 90.1 to 95.3% extraction.

In using these formulae it must be borne in mind that the calculus only rigidly applies for minute variations, but, from a practical standpoint, they can be used even where a large error is to be analyzed. In the above case it is safe to use the calculated ratio only where variation from 4.15 to 5.85 is allowable; and in using the estimated extraction only where a variation between the limits of 90.1 and 95.3% is permissible. The larger mills are equipped with apparatus for weighing and sampling, which makes them independent of this formula; but, in a number of smaller plants, the formula is still used, and the foregoing method of study may prove valuable. To use any of the formulae for gold or silver, it is only necessary to substitute ounces instead of the decimally expressed percentages.

RICH COPPER AND GOLD ORE is reported to have been discovered in the Tchernae district of Central Asia, with a reported richness of 20 to 60% copper. In the neighborhood of Tchimgan, 60 miles from Tashkent, Central Asia, gold deposits are reported to have been accidentally discovered.

Antimony Deposits of Arkansas

By ELLSWORTH H. SHRIVER

Antimony deposits in the State of Arkansas thus far discovered, are confined to the region adjacent to the little town of Gillham on the Kansas City Southern Railroad, in northern Sevier county. Outcrops have been discovered in an area extending about 12 miles east and west by 4 miles north and south. This area, shown

ANTIMONY DISTRICT IN ARKANSAS

in the accompanying map, consists of low hills and broad valleys. The elevation of the railroad station at Gillham is 751 ft. above sea-level. Rolling Fork river, 5 miles west and Cossatot river, 4 miles east of Gillham, drains the region, both being tributary to Little river. The country-rock of a large part of south-west Arkansas is sedimentary and is probably of Carboniferous age. The rock consists of repeating series of fine-grained, blue sandstone and argillaceous shale. The sedimentaries are supposed to have great thickness. After the sedimentation had been completed, disturbances caused flexure of the beds bending them into great anticlines and synclines. The anticlinal apexes are from a quarter of a mile to one mile apart. The disturbances were probably accompanied by great elevation of the temperature as the rigid sandstones have been bent at rather sharp angles. The shales were twisted and broken, and finally were partly metamorphosed to slates. Erosion has taken place rapidly since this action and the débris has been carried to the lower valleys as fast as formed. Some movement occurred after the mineralization was finished.

The stibnite ore was formed by replacement of the shales and slates. The folding of the sedimentaries opened passages through which ascending, hot, mineral-bearing solutions could freely circulate. The solutions broke through the underlying sandstone strata at some point and found their way through the crushed shales where the replacement occurred. Possibly some of the ore was deposited also in cavities. The fine-grained blue

sandstone proved impervious to the hot waters and acted as an impounding dam. Many small beds of sandstone lying within the slate area produced parallel veins, as seen in Fig. 2. The veins in some of the mines show a banded structure. The ore occurs in the form of large lenticular masses. Quartz was deposited at the same time as the stibnite, and forms the gangue of the veins. The ore-bearing rock is the shale or slate, rarely, if ever, the sandstone. The hanging wall is decomposed slate in all cases, and the foot-wall is the fine-grained sandstone upon which the solutions flowed. The ore is cemented to the foot-wall, and varies from a thin streak to about 30 in. wide, while the full lode is from about 2 in. to 5 ft. in width. The strike of the veins is generally a few degrees north of east, and the dip is almost vertical.

Two varieties of sulphide-ore are found; one with large orthorhombic prism-structure, and another with a compact fibrous character. The fibrous ore found near the surface is generally partly oxidized to the tetroxide (cervantite) or to antimony ochre. The prismatic ore

LONGITUDINAL SECTION, MAY MINE

rarely shows oxidation. A typical analysis of the high-grade, dry, sulphide-ore is given below:

	%
Antimony	55.00
Arsenic	0.03
Lead	0.25
Iron	3.04
Silica and carbonaceous matter	11.64
Sulphur (by difference)	30.04
	100.00

The first discovery of antimony ore in Arkansas was made by Robert Wolfe, a pioneer of Sevier county, who found the outcrop of what is known as the West Wolfton mine, in 1873. A person named Batson discovered an

outcrop of stibnite and ochre, 24 in. wide, at what is known as Antimony Bluff on the east bank of Cossatot river in 1874, and the Stewart lode was discovered by Joseph Stewart in 1877. The West Wolfton deposit was worked during the summer of 1877, and in July of that year 25 tons of ore was shipped to Hallett & Co., of London. Antimony Bluff was first worked by the Little Rock Mining Co. in 1876, seven tons of high-grade stibnite and ochre being shipped to Hallett & Co. that year. A narrow vein of jamesonite was discovered near the surface in the Stewart shaft which soon pinched. This is the only known occurrence of jamesonite among the Sevier county deposits. The absence of railroads or good

tion facilities and by their inability to smelt the ore, ceased operations.

Paul Knod of Gillham, worked the May mine in 1902, shipping the ore to Hill & Co., at New York. The majority of the old claims were leased by the American Antimony Co. in 1912. A small amount of work was done during the year but its capital was insufficient to continue. In 1916 the high price of antimony that had prevailed during the winter of 1915-16 stimulated interest in the Sevier county deposits. Early in January, C. M. Fenton of Joplin acquired a large number of these properties. The Valley and Wolfton claims were pur-

TRANSVERSE SECTION THROUGH MAY MINE

TRANSVERSE SECTION THROUGH OTTO MINE

wagon roads in those days discouraged mining and nothing was done toward further exploitation for 10 years. The United States Antimony Co., of Philadelphia, obtained control of the properties known in 1877 and started work. The May, Valley, Otto, and East Wolfton shafts were sunk by this company. A reverberatory smelting furnace was built at Antimony City, a little settlement just across the county-line in Howard county, in 1887. The smelter was not a success, although several experienced men were imported from Europe. The furnace was shut down after two months futile effort to produce a marketable metal. During the remainder of 1887 and in 1888, the United States Antimony Co. freighted ore 40 miles by wagon to Nashville on the St. Louis & Iron Mountain Railroad from which point the ore was shipped to Philadelphia, New York, and Europe. The old stopes at some of the mines, particularly the Otto, are quite large, and the orebody must have been of considerable size. Near the end of 1888, the United States Antimony Co., discouraged by want of transporta-

tion facilities, and the May and Otto were leased. A company was organized under the name of the American Star Antimony Co. with J. G. Battelle, of the Columbus Iron & Steel Co., as president, while the Otto Mining Co. was organized for the purpose of working the Otto mine, 75% of the stock being held by the American Star Antimony Co. Difficulties in obtaining machinery hindered operations and it was late in June before the mines were unwatered and ready for production. The operations of the American Star Antimony Co. aroused local interest, and several new prospects were started in the vicinity of Gillham. The Daisy Mining Co. was organized at De Queen, Arkansas, and had produced a small amount of high-grade ore when work was stopped by dissension among the owners, and the decline in the price of antimony soon discouraged the others. Construction of what was intended to be a first-class smelting plant was started in March by the American Star Antimony Co. under the direction of a Seattle metallurgical engineer. The capacity of the smelter was to be two tons of star antimony

per day. The process was similar to that of Herring-schmidt, consisting of roasting the ore to the volatile oxide in muffle furnaces, condensing the oxide in chambers, and then refining it to metal. The design of the roasting-furnaces proved faulty and they were shut-down in July. An experimental electrolytic plant, with a capacity of 400 lb. of star antimony per day, was also built for the purpose of determining the possibility of recovering the antimony from the furnace residues and also for treating the low-grade ores. The capacity of this plant was later increased to 800 lb. per day.

Mechanical difficulties in the leaching system, due to the faulty design of the mill, together with metallurgical difficulties in the regeneration of the electrolyte that had not been met in the experimental-laboratory work, so increased the cost of operation that it was thought advisable to close the plant until the leaching trouble could be overcome and the other metallurgical difficulties could be worked out on a laboratory scale. The results of the tests have apparently remedied the defects in the system as originally installed. The star antimony produced by the electrolytic process was of an extremely high grade. The cathode metal, after being melted and cast into ingots, analyzed above 99.90% Sb. A typical analysis is as follows:

	%
Antimony	99.950
Arsenic	0.005
Sulphur	0.045
Iron	Trace
	100.000

After the failure of the smelting furnaces, the company made efforts to obtain an engineer familiar with antimony smelting who could design and build a furnace guaranteed to give results, but thus far these efforts have failed.

The accumulation of ore resulting from the failure of the furnaces made it advisable to close the mines on September 15. During the operations of 1916, approximately 367 tons of high-grade ore, assaying above 25% Sb, and 597 tons of 10 to 25% ore were produced. The average daily tonnage of both high and low-grade ore, from the three producing mines was about 12 tons, and the cost of mining was about \$14 per ton, including haulage to the ore-house at Gillham. The American Star Antimony Co. expects to resume operation in the near future.

Gauge-Problem in Rifle-Manufacture

A statement of the present situation as regards the manufacture of both rifles and machine-guns was recently made to Congress by John Q. Tilson, of Connecticut, a member of the House Committee on Military Affairs. Mr. Tillson said that the Government had on hand at the present time approximately 800,000 Springfield service-rifles, and that the two arsenals at Springfield, Massachusetts, and Rock Island, Illinois, by work-

ing three shifts to their fullest capacity could probably manufacture 500,000 rifles per year. There are also about 350,000 Krag-Jorgensen rifles in existence, but their use is not recommended for various reasons, among them being the difference in ammunition.

To increase the output of this type of rifle by manufacture is impossible because of the lack of gauges, jigs, and other necessary tools and fixtures. A large number of these are required for making the service-rifle, which is composed of about 150 different parts. The receiver containing the bolt and the mechanism alone requires 120 gauges for its manufacture. The gauges and jigs can, of course, be made only by expert tool-makers, of whom there are a limited number in the entire country. It is estimated, if all the qualified tool-makers available should be taken off other work, and set to making gauges for the service-rifle, that it would take a year to make enough gauges to permit large-scale production of this one weapon.

On the other hand, there are now in this country, in the hands of private manufacturers, gauges and other equipment for making 15,000 per day of the Enfield rifle, which is the standard British weapon. The question of rapid production of arms then resolves itself into whether we manufacture Enfield rifles chambered for the regular ammunition used by the British army with that weapon, or whether we shall chamber these Enfield rifles for the Springfield ammunition, so that both kinds can be used.

The arsenals are also manufacturing a large number of the new service-pistol, but are not making them fast enough to equip the new officers that will be taken into the service. Both rifles and pistols have felt the high cost of living. The cost of manufacture of the Springfield rifle used to be \$15 and is now \$25.

Shrapnel manufacture also requires a large number of gauges. About 300 are needed for the 3-in. shell, containing 252 bullets encased in resin. It is equipped with a fuse that can be set for any time up to 21 seconds, and there is a black-powder charge at the base. The object of the gunner is to make his shrapnel explode a short distance in front of the target. The bullets then leave the shell in a fan-shaped stream, and the burning resin and powder show the gunner where the shell is exploding.

Several types of machine-guns are in service, including the Hotchkiss, Colt, Marlin, Vickers, and Lewis. The Navy has ordered 1600 Marlin guns for shooting submarine periscopes. About 300 Lewis guns were purchased last summer, and deliveries are now being made of Vickers guns. At present, the Army has only four machine-guns to each regiment, which General Leonard Wood states that we should have one gun to every ten men. While this may be too many, there is no doubt that the present number is ridiculously small.

In general, Mr. Tilson stated that the arms and ammunition now on hand would not be sufficient to equip fully an army of 100,000 men, although a large force could be equipped for drilling alone.

Physical Chemistry of Emulsions

By MARTIN H. FISCHER and MARIAN O. HOOKER

*We have been engaged during the past few months in a study of the conditions which determine the making and the breaking of emulsions. Of the long list of mutually immiscible liquids that might have been chosen for a study of emulsification, we have worked chiefly with water and oil. The mixture of two such immiscible liquids may yield two types of emulsions, as Walther Ostwald first showed; one consisting of oil in water, a second, of water in oil. With much water and little oil, the first type of emulsion is usually obtained; with much oil and little water, the second type. When medium amounts of the two liquids are mixed with each other, either type may be produced, depending upon the methods of mixing. Oil placed in contact with water does not lead spontaneously to the formation of an emulsion. To produce such, the two must be beaten together. The amount of oil that may be emulsified in pure water is very small, in no case exceeding one to two per cent. These emulsions are, however, stable. The oil-particles in such emulsions are rather small, their dimensions lying within the realm of the colloids. These low concentrations of oil in water, therefore, really represent colloid-suspensions of oil in water and possess, not only the stability characteristic of such system, but also their well-known 'saturation limit.'

The term 'emulsion' is ordinarily used to cover the subdivision of one fluid in a second in amounts exceeding these low values. The mixture must, moreover, show a fair degree of stability; in other words, the two liquids constituting the dispersoid must not separate in the course of weeks, months, or years. A temporary subdivision of any quantity of oil in a given volume of water, or the converse, can, of course, be obtained by merely beating the two together. The problem of emulsification therefore resolves itself into the question of how, once the division of oil in water has been accomplished, this can be, or is, stabilized. Contrary to the general belief of different workers who have each tried to discover some one element responsible for this stabilization, a number of different factors evidently play a rôle, the relative importance of which may not only vary in different emulsions, but in the same emulsion under different circumstances. It is generally held that the formation and the maintenance of an emulsion depend upon the slight surface-tension of the dispersing medium, and its high viscosity. While both these factors undoubtedly play a part, their inadequacy in explaining the stability of all emulsions is generally admitted. Not only does the stability of emulsions not universally parallel the surface-tension values of the liquids making up a given dispersoid, but dilute soap-solutions with low viscosity act as better emulsifying agents than more viscid glycerin-solutions. Pickering has emphasized the importance of a third factor in the maintenance of an emulsion,

namely, the development of an encircling film about the droplets of the divided phase through the accumulation in the surface between the oil and the dispersion medium, of finely divided particles of a third substance. But this explanation, too, seems adequate only for selected examples of emulsions.

In reviewing the empirical instructions available for the preparation of emulsions, and in our own attempts to formulate such as would always yield permanent results, we were struck with the fact that their production is always associated with the discovery of a method whereby the water (or other medium) which is to act as the dispersing agent is all used in the formation of a colloid hydration (solvation) compound. In other words, when it is said that the addition of soap favors the formation and stabilization of a division of oil in water, it really means that soap is a hydrophilic colloid which, with water, forms a colloid-hydrate with certain physical characteristics and that the oil is divided in this. The resulting mixture cannot, therefore, be looked upon as a subdivision of oil in water, but rather as one of oil in a hydrated colloid. The amount of colloid necessary for stabilization, at least in the preparation of an emulsion, is rather great. It must be sufficient to bind all the water. The concentrated soaps show a high degree of water-absorbing power and so are among the best emulsifying agents. Very good, too, are blood-albumin, casein, egg-white, and egg-yolk, this last already representing an emulsion of oil in a hydrated protein. Good emulsions may also be prepared, when the temperature is properly controlled, with gelatin. Not only may proteins be thus used, but various hydratable carbohydrates do well. Acacia has long been so used. Starch, dextrin (or dextrinized starches) and, when the temperature is properly regulated, agar, also serve well. Oil can also be maintained in finely subdivided form in cane-sugar solutions or in glycerin, but these emulsions slowly separate. The enumerated substances do not all act equally well. This is because, in the production of a hydrated colloid, they behave differently from both a qualitative and quantitative viewpoint. Best results are obtained with those substances which not only have the power of taking up much water, but which yield liquids of good viscosity with all amounts of water that may be added to them. What is wanted is a relatively homogeneous liquid of good tenacity, by which is meant one that possesses good covering power together with great cohesiveness. The action of casein as a stabilizing agent is particularly instructive. Neutral casein does not absorb much water, and it does not in this form serve for the preparation of an emulsion, but when alkali is added, it develops marked hydrophilic properties, on the appearance of which it becomes one of the best stabilizing agents for emulsions known. It might be thought that the alkali element is so important because it forms a soap in contact with oil, and soap has long been known as an effective emulsifier. While some such action no doubt occurs, it is easily proved that the development of hydrophilic properties by the casein is of first importance because acid (which

*Abstract: *Science*, N. S., Vol. XLIII, No. 1109, pp. 468-472.

when added to neutral casein converts it into a hydrophilic colloid) works quite as effectively as does alkali.

An emulsion breaks whenever the hydrophilic (lyophilic) colloid which holds the aqueous dispersion-means is either diluted beyond the point at which it can take up all the offered water, or is so influenced by external conditions that its original capacity for holding water is sufficiently reduced. Certain emulsions, as those of oil in soap, therefore, tend to break on simple dilution, but agents which dehydrate the hydrophilic colloid act even more rapidly and effectively. What will prove to be

effective agents in this regard depend, of course, upon the character of the hydrophilic colloid that stabilizes the emulsion. When alkali-casein is used, the addition of acid breaks the emulsion, while alkali will break an emulsion stabilized by acid-casein. The same concentration of acid or alkali is without effect upon an emulsion stabilized by a carbohydrate like acacia or dextrin. Since even neutral salts will dehydrate an acid or alkali-protein, they readily serve to break emulsions stabilized by these substances. An emulsion of oil stabilized in soap is also readily broken by alcohol.

Government Copper Report

The Government has completed its report on the copper producing industry for 1916. It states that the smelter production of primary copper in the United States was 1,928,000,000 lb., compared with 1,388,000,000 lb. in 1915, an increase of 39%. The total value of the output in 1916 at an average price of 24.6c. per pound is \$474,288,000, compared with \$242,900,000 for 1915. In the following table the production is apportioned to the States in which the copper was mined. The total is

The total production of new refined copper in 1916 was 2,259,000,000 lb., an increase of 625,000,000 lb. from the output in 1915. The stock of copper on hand January 1, 1917, was 128,055,229 lb. as compared with 82,429,666 on January 1, 1916. The apparent consumption of refined new copper in the United States in 1916 was 1,429,755,266 lb. In 1915 it was 1,043,461,982 lb. The method employed in determining the quantity of copper retained for domestic consumption is shown in the following table, which does not include stocks of copper held by consumers:

	1916	1915	1914	1913
Total refinery output of new copper.....	2,259,387,315	1,634,204,448	1,533,781,394	1,615,067,782
Stock beginning of year	82,429,666	173,640,501	90,385,402	105,497,683
Total available supply	2,341,816,981	1,807,844,949	1,634,166,796	1,720,565,465
Refined copper exported	784,006,486	681,917,955	840,080,922	817,911,424
Stocks at end of year	128,055,229	82,429,666	173,640,501	90,385,402
Total withdrawn from supply	912,061,715	764,347,621	1,013,721,423	908,296,826
Apparent consumption	1,429,755,266	1,043,497,328	620,445,373	812,268,639

made up of fine-copper content of blister produced and of the smelter output of ingot and anode copper from Michigan, in pounds:

	1916	1915	1914	1913
Alaska	113,823,064	70,695,286	24,985,847	23,423,070
Arizona	694,847,307	432,467,690	382,449,922	404,278,809
California	43,400,876	37,658,444	29,784,173	32,492,265
Colorado	9,536,193	7,272,178	7,316,066	9,052,104
Georgia	803,699
Idaho	7,248,794	6,217,728	5,875,205	8,711,490
Maryland	126,965	15,426	12,248
Michigan	269,794,531	288,916,410	158,009,748	155,715,286
Missouri	377,575	306,406	53,519	576,204
Montana	352,139,768	268,263,040	236,805,845	285,719,918
Nevada	100,816,724	67,757,322	60,122,904	85,209,536
New Jersey	4,115
New Mexico	79,863,439	62,817,234	64,204,703	50,196,881
North Carolina	5,961	33,383	19,712	180
Oregon	2,433,567	797,471	5,599	77,812
Pennsylvania	904	422,741	245,337
Tennessee	14,556,278	18,205,308	18,661,112	19,489,654
Texas	86,463	38,971	34,272	39,008
Utah	232,335,950	175,177,695	160,589,660	148,057,450
Vermont	324,400	23,995	5,771
Virginia	1,066,143	50,008	17,753	46,961
Washington	2,473,481	903,661	683,602	732,742
Wyoming	1,784,351	351,871	17,082	262,235
Undistributed	65,479	51,385
Total	1,927,850,548	1,338,009,527	1,150,137,192	1,224,484,098

If to the 1,429,755,266 lb. of new refined copper is added the 594,423,807 lb. of secondary copper and copper in alloys produced during the year, it is found that a total of about 2,024,000,000 lb. of new and old copper was available for domestic consumption.

THE SUBCOMMITTEE ON ZINC, under the committee on raw materials, minerals, and metals, Council of National Defense, is as follows: Chairman, Edgar Palmer, president New Jersey Zinc Co., 55 Wall St., New York; Charles W. Baker, president American Zinc, Lead & Smelting Co., 120 Broadway, New York; A. P. Cobb, vice-president New Jersey Zinc Corp., 55 Wall St., New York; Sidney J. Jennings, vice-president United States Smelting, Refining & Mining Co., 120 Broadway, New York; Cornelius F. Kelley, vice-president Anaconda Copper Co., 42 Broadway, New York; N. Bruce MacKelvie, president Butte & Superior Copper Co., 25 Broad St., New York; Thomas F. Noon, president Illinois Zinc Co., Peru, Ill.; Charles T. Orr, president Bertha A. Mining Co., Webb City, Missouri.

MANGANESE ore imported into the United States for the first quarter of 1917 amounted to 145.720 tons, being at the rate of 48,573 tons per month, as against 48.026 tons per month for the same period in 1916.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

TORONTO, ONTARIO

THE LABOR SITUATION AT PORCUPINE BECOMING WORSE AND SOME MINES HAVE BEEN OBLIGED TO CLOSE DOWN.—TEST FUME CASES DECIDED AGAINST MINING COMPANIES.—AN OFFER TO BUY OUTRIGHT THE LAND OF DAMAGED PARTIES.

Labor conditions at the Porcupine camp have been growing steadily worse, resulting in a marked falling off in production. The four-weekly statement of the Hollinger for the period ending April 22 showed gross profits of \$194,688 as compared with \$210,749 for the previous period, and \$240,175 for the term ended December 1. The mill only ran 72.6% of possible running time. Working costs have shown a steady increase being \$4.25 per ton according to the latest statement, as compared with \$3.76 in December. The force now employed at the Hollinger numbers only 950 men as against 1300 at the beginning of the year. The management does not propose to make any change in the policy of maintaining operation to the fullest capacity possible. It is considered probable, however, that the Dome mines may decide on curtailing production until the labor situation shows some improvement. A party of directors went to the district last week to investigate labor conditions, and a decision on the course to be pursued is expected shortly. The annual report shows a considerable falling off in the ore reserves, which were estimated as of April 1, at 2,250,000 tons of the value of \$11,979,000, as against 2,600,000 tons valued at \$16,120,000 on April 1, 1916. During the year ended March 31, 459,530 tons were treated, yielding bullion worth \$2,171,784, the average yield being \$4.72 per ton. Expenses were \$1,241,562, leaving net earnings of \$929,922. It is estimated that the decrease in ore reserves is counter-balanced by the discovery of new ore-zones and the proving up of the downward extensions of known deposits, and that the only reason why the results of development work were unsatisfactory is that it was so limited in amount. The force employed has been reduced to 375 men.

The McIntyre is now the second largest producing mine in the district. The mill is treating about 530 tons daily, and there are 400 men on the pay-roll. A statement covering the four months ended April 30 shows an operating profit of \$279,563, the ore treated being of an average grade of \$10.43 per ton. The ore already proved for a distance of 1000 ft. on the 1000-ft. level has been showing an average of about \$14 throughout, and as the workings are being opened up into Jupiter ground the gold content is maintained. The management is arranging for the installation of machinery to carry operations 1000 ft. below the present workings. A controlling interest in the Scottish Ontario, comprising 240 acres, about one mile north of Porcupine Lake, has been purchased by a Montreal syndicate. The 10-stamp mill of the Newray is now in operation.

The Tough-Oakes, at Kirkland Lake, is treating 120 tons of ore per day, with a production of approximately \$60,000 per month, employing 200 men and 21 machines. Fifty more men would be taken on if they were procurable, but under present conditions development cannot keep pace with the requirements of the mill. The Lake Shore has a large quantity of ore blocked out on the 200 and 300-ft. levels, and is receiving the machinery for its 100-ton mill. The Beaver Consolidated has made its second payment of \$75,000 on the Kirkland Lake mine. The Sylvanite has closed down, owing to the shortage

of labor and the high cost of materials. The Wright-Hargraves has raised funds for further development by making a new stock issue of 200,000 shares, which have been taken up at 40c. per share.

Cobalt has not been so seriously affected by labor shortage as Porcupine and the other gold camps, the pay at Cobalt being somewhat higher on account of the bonus given so long as the price of silver keeps up. Production is well maintained at present, but much uncertainty prevails as to the result of the agitation for increased wages.

An important judgment has been given in several actions for damages brought by residents of the Sudbury district against the Canadian Copper Co. and the Mond Nickel Co. for losses alleged to have been occasioned by poisonous fumes from the smelters of the companies. These cases have been before the courts for some time, and six actions were consolidated for one trial, which extended over a period of 34 days, special sittings being held at Sudbury and Toronto. Judge Middleton announced his decision on May 31, giving four of the plaintiffs damages against the Canadian Copper Co., amounting in the aggregate to \$3350, and two others \$1900 against the Mond Co. The application for an injunction against the companies was refused, the judge holding that though the fumes from the smelters might be a nuisance, individual rights could not be maintained against the interests of the whole community, and the court could not destroy the Sudbury mining industry, even though it destroyed a few farms. In such cases, he said, liberally estimated compensation ought to be awarded, and he had been assured that the mining companies were ready to purchase the holdings of those who suffered by their operations at a price in excess of their value. The actions were in the nature of test cases and a number of other suits which were suspended until a decision was reached will now be proceeded with.

LEADVILLE, COLORADO

MINERS DEMAND FURTHER INCREASE IN PAY.—A BI-WEEKLY PAY-DAY.—A NEW AND IMPORTANT DEVELOPMENT ENTERPRISE AT CANTERBURY HILL.

The labor situation is again the centre of interest in the Leadville district as a result of the recent sitting of the State Industrial Commission here and subsequent meetings of the local branch of United Mine and Smelter Workers. The union appealed to the commission last year when the miners asked a general increase in wages of 75 cents per day. No action was taken at that time, however, and the operators voluntarily granted a total raise of 50 cents per day by making two increases during the year. This action on the part of the managers brought the wage-scale from a basis of \$3 to \$3.50. Early in the present year, the union amended the previous demands and asked that the commission recommend an increase in wages of \$1 per day on the new basis, which would bring the scale up to \$4.50.

The hearing was held in the county court room on May 21, 22, and 23, before Hiram E. Hilts, chairman of the Industrial Commission, and Commissioner A. N. Parrish. Evidence covering the local living conditions with particular reference to the increase in the cost of commodities, clothing, and rentals, and the general working conditions at the mines was secured from representatives of the union; while the operators and man-

agers testified regarding the increased cost of ore production, which, they stated, offset any increase in the value of the product.

After securing all available evidence in the matter, Commissioners Hilts and Parrish returned to Denver and conferred with their colleagues, George W. Densmore and J. A. Warren. Following ten days' deliberation on the question, the commission announced a decision opposing the demands of the union.

In a report on the situation, the commission found that living conditions at Leadville are as good as or better than in any other metal-mining district of Colorado. There has been very little increase in rentals, and although the cost of provisions has increased materially there has been only a slight increase in the cost of board. The cost of clothing was found to have increased to a small extent. Working conditions at the mines and relations between employer and employee were found to be satisfactory.

The commission also found that approximately one-half of

WOLFTONE MINE, CARBONATE HILL, LEADVILLE

the miners in the Leadville district are employed on prospecting, development, and non-productive work; and that a considerable number of the men are developing orebodies that would not be marketable under normal conditions. It was found that there has been a large increase in the market price of zinc, copper, and lead, but that the operators do not receive anything like the full benefit of the increase. Nearly all the ores now produced were reported to be comparatively low grade and the margin of profit so narrow that any material increase in the cost of production at this time would work a serious injury to the mining industry of the Leadville district.

On these grounds, the commission found the demands of the employees for an increase in wages to be unjustified, but the employers were recommended to inaugurate a semi-monthly pay-day to allow the employees to take advantage of purchasing provisions and commodities on a cash basis.

The decision of the commission is wholly unsatisfactory to the union; and rumor of forcing the issue has since kept the district in a state of uncertainty and anxiety. Two meetings of the union have been held since the decision of the commission was received, and the speakers have disclaimed any intention of striking, although they declare that some form of relief from present conditions is imperative. They ask that the operators hold a conference with union representatives and discuss the question fully. Many of the men state that any increase in wages received at this time would give only temporary relief, because they believe the prices of provisions would again be raised to a new plane that would entirely offset the gain in pay. It is this control of the merchants over food prices, they state, that should be investigated before taking other action.

The Canterbury Hill tunnel—a project that for years has been the dream of Leadville mining men—is about to be undertaken. Arthur A. Garrett, an experienced mining man of the district has secured a 20-year lease on a tract comprising 425

acres on Canterbury hill extending from the upper Arkansas valley to Little Evans gulch, including the Roseville and Alta ground, the Minneapolis, and Canterbury. Through this territory he has mapped out the course of an adit that will cut the ore-bearing formations after passing through the wash at a distance of 600 ft. from the portal, and will continue in the ore-bearing formation for a total distance of nearly 7000 ft. The elevation of the bore will be 10,100 ft.—200 ft. lower than the Yak and 1200 ft. lower than the Silver Spoon tunnel in Prospect mountain. This project will open to development an area larger than the present productive portion of the Leadville district.

The Canterbury hill area has never been developed below the blue lime, but several shafts put down from the surface encountered large bodies of iron at the contact between the gray porphyry and the blue lime. Values as high as 193 oz. silver were obtained from samples taken from the Canterbury shaft. Development in these workings was checked at the time by a heavy flow of water that resisted all efforts of draining. The adit will cut under these workings several hundred feet and will drain the entire area. The adit will at no place be more than 800 ft. below the surface and at several points it will be within 500 ft. This factor is important in that it allows for the sinking of air-shafts, and shafts for the hoisting of waste and the handling of men, that may be sunk with comparatively small expense.

The portal of the adit will be in the upper Arkansas valley about a mile and a half above the Denver & Rio Grande depot. It will follow a course through Canterbury hill swinging from east to south-east to maintain its course in the ore-bearing region.

NICARAGUA

VALUABLE MINES CLOSED BECAUSE OF INABILITY TO PROPERLY FINANCE THE PROPERTIES OWING TO THE WAR.—A VIRGIN COUNTRY UNPROSPECTED THAT AFFORDS ABUNDANT OPPORTUNITY TO ENTERPRISING CAPITAL.

The Sta. Francisca mine, formerly belonging to an English syndicate, and nearly 48 miles from the town of Leon, has been shut-down ever since the beginning of the European war, prevented by it from being re-organized. This is regrettable, as this mine, formerly a big gold producer, while in the hands of the Australian Morgan, and his associates, could still be made to yield considerable results, if worked with the proper pumping-equipment. Hot water prevented the tapping of the lower levels, which are practically unknown, except for some very rich assays obtained from the St. Luis part of the property, while under the management of J. J. Calderwood. As these hot springs are of volcanic origin and contain sulphur, the company found itself financially unable to purchase the necessary pumping-outfit and therefore had to close down. It is understood that John May, of Corinto, now owns the property.

The La Gracia mine, about five miles from San Juan de Limay, was purchased recently by the Butters Devisadero interests from Dr. Burno Mierisch and associates. This mine, which formerly was known only for its richness in silver, has also been shown to contain gold, that has been developed by Dr. Mierisch, following the suggestions of an American mining engineer who examined the property about seven years ago. The purchasers have been prevailed upon to build a cart-road which would enable them to haul their machinery from the next railway station, Leon, which is about 100 miles distant. This road, built by the mine, will prove a great benefit for the numerous farming interests of the district and to the hinterland of Segovia, as formerly all freighting had to be done on muleback. It will also help the development of the Limay mining district, which contains some valuable prospects that so far are practically untouched except for some little work done by the Castellón interests and those of General Ortiz, a

prominent miner from the neighboring Republic of Honduras. The writer of this was shown some specimens from this district that were free-milling and of unusual richness. A real prospector is an unknown quantity in this country, as the surface picking done by the natives of the country is anything but thorough prospecting.

The La Leonesa mine, near Matagalpa, which is owned by an American-English company, has been practically shut-down for the last eight months, as the main shaft was lost through the inefficiency of the pumping apparatus, and the chief value of the mine is in the lower levels now under water. The foreign staff was reduced from about 20 to 3 employees. The manager, Mr. Thomas, returned recently from a trip to London, where it is presumed he went to obtain new machinery. It is hoped that he has been successful in this, as the closing down of this property was a great blow to the district, as it was the main support of this region, apart from a few coffee ranches.

NEW SOUTH WALES

MINING INDUSTRY HAMPERED BY STRIKES, BUT PRODUCTION IS NEVERTHELESS LARGE.—TOTAL MINERAL PRODUCTION NEARLY \$1,700,000,000.

In the annual report for 1916 just published the under secretary points out that the output for 1916 was worth £10,975,742, which is the third highest in the history of the State, and exceeds that of the year 1915 by £911,173. The high prices ruling for the industrial metals, notably copper, are mainly responsible for this gratifying result, and were it not for a period of industrial unrest at Broken Hill and in the Cobar field in the beginning of the year, and the coal strike towards its close, which resulted in the temporary closing down of many of the principal mines, the output would have been even more satisfactory.

The output of coal was 8,127,161 tons valued at £3,336,419 for the year 1916; a decrease of 1,321,847 tons and £88,211 in value from that recorded for the year 1915. The value for the year's production of the silver-lead mines was £4,084,623, which was £763,522 in excess of that for the year 1915.

The total aggregate value of the mineral production of New South Wales to the end of 1916 is £273,154,084. Coal heads the list with a production valued at £83,356,873, silver-lead follows with £75,328,237, and then gold with an aggregate value of £61,649,740.

The following statement of the value of the output for each decade illustrates the progress of the mineral industry during the past 50 years:

1867 to 1876.....	£ 18,129,455
1877 to 1886.....	22,422,983
1887 to 1896.....	46,772,464
1897 to 1906.....	60,772,488
1907 to 1916.....	100,593,702

COBALT, ONTARIO

AN APPEAL FROM AN INJUNCTION GRANTED IN THE PETERSON LAKE TAILING CASE, PENDING.—OPERATORS FAIL TO RECOGNIZE THE MINERS' UNION OF NORTHERN ONTARIO.—AN ACTIVE SEASON ANTICIPATED IN THE NEW MATACHEWAN DISTRICT.

The injunction granted to the Peterson Lake Mining Company, restraining the Dominion Reduction Company from taking tailing-slime and sand out of Peterson Lake, has been lifted, but as an appeal against the removal of the injunction has been granted, the Dominion Reduction Co. cannot yet start the treatment of this tailing. Their second flotation-unit together with grinding-equipment is about completed. The

completion of this unit would enable the Dominion Reduction Co. to treat about 400 tons per day. The tailing in the lake assays between four and five ounces per ton.

An Order-in-Council has been passed by the Ontario government, relieving all claim-holders from the performance of assessment work on their claims in northern Ontario during 1917. The order does not cancel 1917 assessment work, but extends the time limit one year.—Vein No. 18, at the Chambers-Ferland mine, Cobalt, is showing up well under development.—The Beaver mine has now completed a 100-ft. raise on the vein recently found on the 1600-ft. level. The ore in the vein is good.—The La Rose mine management is contemplating re-opening its Violet mine east of the O'Brien.

A few weeks ago the Miners Union sent out their demands for an increase base wage-scale to the mine operators of northern Ontario, and asked for a conference, a reply being requested before the end of May. As far as can be learned no mine operators have conferred with the Union. Practically all the men in the Cobalt mines, with the bonuses, are receiving now as much as, and in some cases more, than the proposed Union scale, so that the action of the men employed at Cobalt is purely a move for recognition of the Union. The syndicate that purchased the Reeves-Dobie property in Gowganda a few months ago, has incorporated the Reeves-Dobie Mines Ltd. with a capital of \$2,000,000. The officers, of whom Charles Ward is president, are all from Rochester, N. Y., and vicinity. The directorate and twenty of the share-holders are now visiting Gowganda. S. Christopherson, the mine-manager, is at present taking out some high-grade silver ore from an open-cut on a vein recently found.

There will be an active summer in the new Matachewan gold district, which includes part of Powell and Cairo townships. Weldy Young has a number of men at surface work on his claim, where some of the best discoveries were made last fall. Homer Sutcliffe has a party of engineers at work on an extensive water-power survey on the Montreal river near the new finds.

JOHANNESBURG, TRANSVAAL

THE STATES MINING COMMISSION REPORTS UNFAVORABLY ON STATE MINING ON THE RAND.—ENGINEERS ENDEAVOR TO SOLVE THE DIFFICULTIES OF HEAVY FLOW OF WATER IN DEEP MINES.

The majority of the States-Mining Commission have reported against the principle of the Government adding to its responsibilities that of State-mining, principally on the grounds that mining is a risky and speculative business and the Far East Rand is no exception to the rule. These views expressed by the majority of the commissioners have caused no surprise, and as the Minister of Mines, long before the appointment of the State Mining Commission was contemplated, expressed the view that the Government was not desirous of adopting State-mining, it is certain that as far as the present Government is concerned the right of future working of the Government mining-areas in the Far East Rand, will, as heretofore, be put up to Lender. There were two minority reports, one by Mr. Roos, the leader of the Nationalist party in the Transvaal, and the other by Mr. Miller of the Labor party. Mr. Roos thought that too much importance was attached to the mining risks of the proved portions of the Far East Rand, and that if the mining-houses were prepared to pay for the right of developing designated Government areas on the Far East Rand, the risks were not too great for the Government to undertake, especially as the areas belonged to the Government. He was in favor of the Government adopting a modified system of mine development on its own areas, but was not in favor of acquisition by the State of privately owned areas for mining purposes. Although not included in the reference to the Commission, Mr. Roos further advocated greater control by the

Government in working of Government-owned gold-mining areas and diamond mines, particularly over the sale of diamonds and the operation of a monopoly in the sale of South African diamonds by a private syndicate as at present. Naturally, in labor circles the recommendations of Mr. Miller, that the State should adopt mining as one of its duties, are heartily supported, but with the experience in South Africa of State-owned railways to guide them, few people outside the Labor and Socialist parties are in favor of pure and undiluted State mining.

It has been decided to try the cementation-process in the damming back of the water in the Angelo Deep part of the East Rand Proprietary Mines. It will be remembered that at a depth of 4000 ft. from the surface, fissures yielding 4,500,000 gal. of water per day were encountered and considerable difficulty was experienced in controlling the flow, even when strong dams for that purpose had been constructed. Although the cementation method of controlling water has been used for many years on the continent of Europe, and lately has been introduced with success in England, its use at the East Rand Proprietary Mines will be the first instance of its trial on the Rand, where apparently there is much scope for its employment. The mode of application at the East Rand Proprietary Mines will be to bore holes in close proximity to the water-fissures and by means of a pump to force a mixture of cement and water under pressure into these holes, the cement subsequently setting and preventing the escape of the water. In this case a pressure of at least 1000 lb. per sq. in. will be necessary with probably one part of cement to 25 parts of water. Some fissures take two tons of cement to seal off the water and the result of the experiment will be watched here with considerable interest.

CRIPPLE CREEK, COLORADO

HIGH-GRADE ORE FOUND IN SEVERAL PROPERTIES IN DIFFERENT PARTS OF THE DISTRICT.—LESSEES SUCCESSFULLY OPERATING.
—OLD MINES REHABILITATED BY LESSEES.

Important and rich discoveries are reported from Raven, Ironclad, Beacon, and Tenderfoot Hill properties, owned by the Elkton Consolidated Mining & Milling Co, the Jerry Johnson Mines Co., the Gold Dollar Consolidated Mining Co., and on the privately owned Queen Bess claim, on Tenderfoot Hill.

On the Elkton property, on Raven Hill, lessees are mining and shipping ore running close to 4.5 oz. in gold per ton, from a new ore-shoot under development at the 900-ft. level. This is on the Walter vein, near to its junction with the main Elkton lode. Settlement was made last week on a 21-ton shipment at the rate of \$89.20 per ton.

On the Jerry Johnson mine, L. S. Cox, a sub-lessee from Frank Caley and son, operating at the 400-ft. level, has cut the upward extension of the Caley shoot that is producing steadily from the stopes above 600 ft. The streak is 4 in. wide and assays from \$800 to \$1200 per ton, and that the ore as broken about 2 ft. wide will ship at 2 oz. gold, is considered a conservative estimate.

The Cripple Creek Deep Leasing Co., operating below the 600-ft. level, has entered ore under the Caley shoot at the 600-ft. level by a raise through from their 850-ft. level, and grab samples range from \$27 to \$43 per ton.

H. C. Harris, the Waugh Drill Company's district agent, and John Bernard, of the Elkton, leasing on the north end of the Gold Dollar company's Beacon Hill property, now operating through the Husted shaft, long idle, have cut four new veins. The hill, east of the shaft, is virgin undeveloped territory. Grab samples from the third of these veins, or rather from the shoot at the junction of the vertical with a flat vein, returned close to 3 oz. gold, with selected samples of 50 oz. or better, to the ton. This lease will commence production by the end of the week.

The Hanewald Brothers and associates, of Leadville and Denver, are responsible for the Tenderfoot Hill discovery. A new ore-shoot has been opened up by a winze 100 ft. below the 600-ft. level of the Mollie Kathleen shaft, through which the lessees are operating the Queen Bess property adjoining. Ore is being sacked for shipment that will run better than 5 oz. gold, and two cars were loaded out the first of the week of an estimated value of \$40 per ton.

The new ore-shoot opened up by J. L. Wilson, of Cripple Creek, at a depth of 515 ft., by a winze sunk below the Trail-tunnel level, on Bull Hill, has been opened up 110 ft. long and the stope, which has carried up 60 ft. is producing ore from a 4-ft. vein that runs from \$8 to \$20 per ton without sorting.

Water has been encountered in the Dillon shaft of the Granite Gold Mining Co., on Battle mountain, at a depth of 1776 ft.,

CRESSON CONSOLIDATED MINE, CRIPPLE CREEK DISTRICT

and sinking has temporarily ceased. The deepest working-level of the Dillon is 1600 ft., and at this depth a strong ore-shoot is under development. The Granite company is making a heavy production from the Dillon and in May the output approximated 3,000 tons with an average value of \$20 per ton.

The Carolina company, operating the Ajax mine adjoining the Granite Gold Mining Co., is cutting a station at a depth of 1800 ft. Sub-lessees of this company, in 12 sets, are developing their several blocks of ground, and the majority of them are producing. The Ajax properties, formerly owned by The Ajax Gold Mining Co., are now owned by E. A. Colburn, of Denver, who was president of the company.

Twenty-eight cans of concentrate was forwarded by express to the Colorado Springs mill of the Portland Gold Mining Co., last week, from the Independence and Victor mills of the company, on Battle mountain. The cans have an estimated value of from \$800 to \$1000 per ton, and this is the heaviest weekly shipment sent out from the local plants to date. The company is concentrating \$2 ore from the ore-house waste and dumps.

The Victor mine, on Bull cliff, formerly owned by the Victor Gold Mines Co., and now by the Smith-Moffat Mines Co., of Denver, is again active. The lease held by Math Korf, of Cripple Creek, has been transferred to the Komac company, organized to operate the property. An electric-hoist and compressor have been re-fitted and are in use.

A 100-hp. electric-compressor has been installed at the Rose Nicol shaft on the north-west slope of Battle mountain by the Camp Bird Mining & Leasing Co., of which J. H. Nichols is superintendent, and the Arkansas Valley Railway Light & Power Co., has extended a power-transmission line to the mine from the Six Points transformer-station, on Bull hill. The Camp Bird company holds a six-year lease on the Rose Nicol Gold Mining Co.'s property, and development work on an extensive scale is planned.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—Four carloads of mining-timbers for the Hardenberg mine have arrived at Martell and are going to the property, where sinking the shaft is proceeding. With an increased depth of 300 ft., the future of this mine seems assured. The shaft will intersect the vein at a depth of 1500 ft., after which new levels will be opened. During former operations, the work was confined to the 850 and 1000-ft. levels, and ore-shoots of good grade were discovered but development work was hampered by lack of funds. The W. J. Loring Company is now working this mine.

After a long delay, the parts necessary to complete the Old Eureka's electrical equipment have arrived, and the new hoisting-machinery and large head-frame have been working well for over a week past. An immense amount of work has been done in bringing this old property to its present stage and there yet remains much to do before it can again become a producer, but with the modern equipment rehabilitation will proceed rapidly. The fact that the shaft from about the 1600-ft. level to the bottom was found to be single compartment, which required widening and re-timbering, has been a task of no small extent, but when finished the entire shaft will be in excellent working condition. Cleaning out and repairing old levels and getting them ready for work will also take time, but good progress is being made. The entire plant presents a business-like appearance.

Shaft-repairing is in progress at the Kennedy mine and repairs are also under way at the tailing dam, where the retaining-wall was undermined, the break having been caught up sufficiently to permit the resumption of milling after a short shut-down.

Sutter Creek, June 16.

BUTTE COUNTY

(Special Correspondence.)—Natomas Consolidated has acquired a large area of proved land near No. 4 dredge and is making preparations for dredging. Repairs have been made to boats No. 1 and 3. For several months the company has been carrying on experimental dredging of old tailing, and the results are reported as favorable.

A compressor and Denver drills have been installed at the Triumph mine, near Lumpkin, and development has begun. The mine workings and roads have been repaired and telephone connections will soon be made with Forbestown. It is stated considerable ore of good grade is exposed. M. B. Sears is manager.

The Springer Consolidated Mines Co. has erected equipment at its mine about one and a one-half miles from De Sabla. The plant contains a crusher and four ball-mills, having a capacity of 300 tons. The ore occurs as a huge dike about 300 ft. wide and traceable for miles, the material being low-grade. It is planned to work the deposit with steam-shovels. Charles M. Schwab and other Pittsburg men are interested.

New pumps have been installed at the Royal Drift gravel mine, near Forest Ranch, and development is progressing with three shifts. Good gravel is reported at several points. J. Allen Veatch, the manager, is expected back from Panama in a short time to resume charge of affairs. In his absence development has been directed by Forrest H. Snow.

The Oroville Dredging Co. has started the prospecting of wide areas along Bear river, in Yuba county, to determine the

feasibility of dredging. Some dredging was done in the district years ago, but with varying results. With large modern boats it is thought the ground can be profitably mined. G. C. Aaronson is in charge of the prospecting crew.

Oroville, June 18.

DEL NORTE COUNTY

(Special Correspondence.)—The mines mentioned below are in California, though Waldo, Oregon, is the nearest post-office:

The Britten and Wilson copper mine, on Patrica creek, is in operation, and some rich ore is being taken out. There are 800 ft. of adit, and 60 ft. of shaft on the property. They are now running a 500-ft. adit to cut the vein 200 ft. below the shaft. J. N. Britten is in charge of the mine.—The Lucky Boy, a copper property 16 miles south-west of Waldo, has been under lease to Portland parties for some time, but they were unable to handle it, so a new company is examining the mine and reports a large body of high-grade ore in sight. The property is owned by Otto Anderson.

The chrome property 25 miles north-east of Crescent City, owned by G. W. Gravin, has been leased by M. A. Delano, of Grants Pass. A noteworthy feature of this ore is its platinum content. Samples analyzed by the Bogardus Testing Laboratories, of Seattle, showed chromium oxide 62.08%, ferrous oxide 30.13%, sulphur 0.06%, phosphorus 0.11%, silica 5.71%, platinum 0.04 oz. per ton.

The Home gold mine, on Monkey creek, is to be re-opened under direction of J. N. Britten. It is owned by O. F. Samson, of Seattle, and has 2100 ft. of adit. There are accommodations for 40 men at the mine.

Waldo, June 16.

(Special Correspondence.)—The Tysen chrome property, 18 miles north of Crescent City, and 3½ miles from the stage-road, has 400 tons of ore ready for shipment. John Hampshire, Grants Pass, Oregon, of the American Exploration Company staff, is in charge. The ore is to be shipped by steamer to San Francisco.

Crescent City, June 14.

MARIPOSA COUNTY

(Special Correspondence.)—The Early mine, near Jerseydale, which has been idle for nearly a year and a half, pending the outcome of litigation, has resumed operations with 30 men. A mill is under consideration by the owners. Geo. H. Hook is superintendent.

Jerseydale, June 12.

SAN BENITO COUNTY

(Special Correspondence.)—The district about New Idria is showing increasing activity in the development of mineral resources. The Aurora quicksilver mine has been re-opened, and 60 men are at work at the large magnesite mine five miles from here.

New Idria, June 14.

SHASTA COUNTY

(Special Correspondence.)—C. L. Wilson, of San Francisco, who controls the Bell Cow group of gold mines, says of that property: It is 45 miles south-west of Redding, on the middle fork of Cottonwood creek, and on the north slope of Arbuckle mountain. The geology of the district has not been carefully studied, but the rocks generally are slate traversed by dikes of porphyry. There are 20 claims in the group, of which three are partly developed by 10 adits, each of which is driven on a

separate vein. These veins, which run north-south, are from 3 to 20 ft. wide and carry an ore that assays from \$7 to \$75 per ton. The sulphide mineral present is practically confined to galena and mispickel. Pyrite, chalcopryrite, and blende are thus far generally absent in the ore. The concentrate obtained in milling this ore runs from \$175 to \$300 per ton.

There is a system of cross-veins branching out from the main veins, at an angle of 45°, that are free from sulphides, but which do carry gold, some of the ore being high-grade. These veins are 4 to 5 ft. wide.

The principal development is a cross-cut adit, known as tunnel No. 1, now in 500 ft., that has already crossed three veins, but the adit has passed through them at points outside of the ore-shoots, and the quartz there is low grade. Drifts will be run on each of these veins. This adit will give a maximum back of 1500 ft. on the veins, and thus afford the least expensive method of mining. At present the property is equipped with a 5-stamp testing mill. Flotation tests also are to be made, as it is thought the ore will be amenable to that process, and that it can be applied with success. Another advantage at these mines is abundance of free water power, and timber sufficient for mining purposes.

Redding, June 20.

SIERRA COUNTY

(Special Correspondence.)—The adit at the Orient mine is in 125 ft. and is expected to reach the orebody within 125 ft. further. At the present rate of progress the work will be completed the first week in July. The Orient formerly produced a great deal of gold and is expected to employ a large force soon.

Vigorous work is proceeding at the White Bear gravel mine, operated under bond by John Costa. In the main drift, sand and fine gravel has been entered and a winze is being sunk to bedrock. Work is proceeding on what is believed to be the east rim of the White Bear lead, where exceptionally rich gravel was found years ago by W. J. Belcher and associates.

At the Monarch Consolidated mine, at Sierra City, all work is concentrated on early completion of the main adit, being driven to open the vein. Work on the upper levels has been temporarily suspended and the mill hung up. It is planned to produce all ore in the immediate future from the new adit, and to later open the orebody by a still lower adit.

The Tightner mine at Alleghany continues to produce rich ore and to pay substantial profits. Most of the ore now going to the mill is of medium grade, but occasional pockets of rich quartz are found. It is stated that the gold output of the Tightner to date exceeds \$1,500,000.

Hydraulic mining is active at Brandy City, Howland Flat, Port Wine, and other Sierra county districts. At Brandy City four to six giants are constantly operating, and abundant water indicates a long season. The mines are controlled by the Brandy City Hydraulic Mines Co. of San Francisco.

Downieville, June 19.

IDAHO

CUSTER COUNTY

(Special Correspondence.)—The board of directors of the Empire Copper Co. at the meeting held June 8, at Salt Lake City, declared the regular quarterly dividend of 5%, payable July 1, to stockholders of record June 25. The board also subscribed for Liberty Bonds to the amount of \$50,000. The bonds will be distributed to stockholders at a later date in lieu of an extra dividend, which had been contemplated. During 1916 this company paid dividends totaling 17% on the capital stock, and thus far in 1917 has paid 20%, including the Liberty Loan investment.

Extensive exploration and development work is being carried on, under the direction of L. F. Clemmons, with satisfactory results. On June 15 a contract was let for driving a 560-ft. four-compartment vertical raise to connect the Alberta and Davis levels. Installation of a \$15,000 boiler and compressor-

plant at the Cossack tunnel is nearing completion, and upon the receipt of approximately 10,000 ft. of 4 and 5-in. black-pipe, work on the driving of a 1007-ft. incline-raise from the Cossack to the Alberta level will be begun. Bids have been received for the construction of a 16,300-ft. tramway to connect the mine with the smelter loading-site and the contract will no doubt be let in the near future. This tramway will do away with the expensive Shay-road operation. F. A. Behling is manager.

Mackay, June 14.

MONTANA

LEWIS AND CLARK COUNTY

(Special Correspondence.)—Recent development in the Drumlummon mine has disclosed 7 ft. of ore in the Maskeline adit-level just south of the old No. 2 station. The average of this width is above 2 oz. gold and several ounces silver. The vein had been stoped along this orebody, which was supposed to be the hanging wall. The extent of the ore has not been determined, but development proves that it extends below the level, above it, and to the south. The mill of the St. Louis company, now operating the Drumlummon, is treating 100 tons per day, has ample ore in sight, and is developing reserves which assure extended operations.

The Gloster mill is treating 175 tons per day of which upward of 100 tons is coming from the Shannon mine, of the Barnes-King Development Co. At the latter, development is proceeding on the 500-ft. level on some of the best ore in the mine. This is gratifying to the company and reassuring to other operators in the Mt. Pleasant district.

The Marysville Gold Mining Co. continues the development on the Blue Bird and Hickey group, the Mt. Pleasant, and Spokane. Driving is proceeding in ore of good average mill-grade, and the reserves of ore developed justify the contemplation of milling facilities. At the Spokane mine of this company the raise from the upper adit has holed through to the 60-ft. level of the old shaft on the slope of the mountain. The value of the ore here ranges up to \$80 per ton. This vein is in granite and seldom carries above 2 oz. of silver.

For the past year local interests have been developing the Looby and Rock Rose mines of the Cruse Consolidated company, and has reached a point at which the operators feel justified in proceeding on a more extensive scale. Efforts to finance the proposed work are meeting with success, assuring the rapid development of the mines and early shipping. The Northern Pacific railway is installing a loading-spur at the Ft. Harrison branch to facilitate shipments of ore and supplies. The Rock Rose shaft is being sunk to the 300-ft. level. As soon as this work is completed, the development of the new vein recently encountered on the 200-ft. level, and cross-cutting for the same on the 100 and 300-ft. levels will be pushed.

At the Helena mine the Helena Mining Bureau has encountered shipping ore in extending the shaft. This will enable the local syndicate to commence shipments of selected ore in a few weeks.

On the True Friend and Cross Fire claims John A. Rowand is sinking and has shipping-ore in the old incline, which he is deepening. These claims lie west of and parallel with the Helena mine, the latter apparently on the northern extension of the Looby.

A number of outcrops throughout the Grass Valley basin give promising returns on assay, but, as yet, the operators have not been in a position to give them the attention they merit. With the work more generally extended, it looks as if the district would become a producer of more than ordinary importance. The value is in gold, silver, and lead, lightly mineralized quartz veins carrying gold almost exclusively, while the silver-lead veins carry from one to four dollars in gold.

Geologically, the district is analogous to that of the mineralized area of Marysville, that is, proximity to the monzon-

ite, slates, and intersecting diorite-porphry dikes, marking the similarity.

Helena, June 18.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—Negotiations have been practically consummated for the control of the Florence mine by the Red Hill Florence Co. Under the plan presented to majority holders of Florence stock, the Red Hill Florence owners require at least 600,000 shares, giving them undisputed control, upon which they have agreed to liquidate the indebtedness of the Florence Goldfield Co., amounting to about \$50,000. The company is at present in the hands of a receiver. Culmination of the deal will be followed by extensive development of the Florence mine from the Red Hill-Florence shaft. Considerable work is going forward in Red Hill-Florence territory. On the 500 level two shifts are driving to open the Florence vein.

It is reported that as soon as the Goldfield Consolidated Co. can make arrangements for the marketing of a larger quantity of flotation-concentrate the second 500-ton flotation-unit will be operated, chiefly on ores from the Atlanta, Kewanas, Jumbo Extension, and other properties, that are now shipping to smelters, but have no market for the lower-grade gold-copper ore. It is understood some difficulty is being experienced in the marketing of flotation-concentrate.

Preparations are being made for the immediate resumption of work at the Triangle mine near Diamondfield. J. K. Turner has been retained as consulting engineer. The property adjoins the Daisy mine and yielded some rich ore when last worked. The company has been reorganized on an assessable-stock basis.

Goldfield, June 20.

NYE COUNTY

(Special Correspondence.)—A powerful electric sinking-pump has been installed in the Victor shaft of the Tonopah Extension, and construction of the auxiliary electric-power plant is proceeding rapidly. Within 30 days the management expects to resume sinking of the shaft, which is now 1759 ft. deep. Preparations are also being made for extensive development in the lower workings. The mill is crushing 2380 tons per week, with most of the ore coming from workings adjacent to No. 2 shaft.

The Tonopah Belmont Co. has declared a quarterly dividend of \$187,500, payable July 2. The Shoestring vein, recently intersected north-west of the shaft on the 900-ft. level, is showing improvement. It is 20 in wide. The Mizpah-Fault vein on this level has widened to 2 ft. of fair-grade ore. The Rescue vein is 16 ft. wide at this point, and is becoming smaller. The South vein continues to show 2 ft. of good ore. The mill is treating approximately 2450 tons per week.

The discovery of the Ohio vein near the centre of the California claim of the West End has created much interest. The vein is flat and has been opened for 200 ft. It appears to be trending toward the MacNamara, with 1300 ft. along its strike still in the California. A heavy tonnage is going to the mill.

Rumor of a possible consolidation of the MacNamara and Rescue Eula companies are in circulation. Should such an arrangement be made it is probable the MacNamara mill will be operated on ore from both mines, in addition to custom ore, of which a large tonnage is available. It is also rumored that the MacNamara company will begin a search for the continuation of the Ohio vein, lately found in the adjoining West End property.

Late reports from Golddyke are to the effect that litigation over the Keystone property, also known as the War Eagle, is being adjusted, and that preparations are being made for a more vigorous development of the gold-bearing deposit. It is a lively camp, and considerable prospecting is going on. Tonopah interests have taken options on several claims.

Tonopah, June 20.

(Special Correspondence.)—The clean-up of the sluices of the Round Mountain Placer Co., for May, resulted in a recovery of \$52,000, according to the statement of L. D. Gordan, general manager. There still remains in the bed-rock cuts, it is thought, an amount equal to 15 to 20% of the sluice yield. It is expected that the June clean-up will be larger than that of May, in which were many nuggets. The water supply has been sufficient thus far, and promises to hold out well for some time longer.

Round Mountain, June 16.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The last clean-up at the Mogollon mill amounted to 1400 lb. of bullion and 3½ tons of high-grade concentrate. The high price of silver has increased the value of dump-ores in the district to a point where they can be worked at a good profit. The Socorro Mines Co. is milling a considerable tonnage of dump-rock from the Little Charlie property and other dumps will no doubt be handled.

The Oaks Co. has a gang of men building a new road to its Central shaft. The head-frame is being remodeled and put in condition for extensive work. Ore shipments are being made daily by this company from the Maud S. mine.

The Pacific mine is now shipping 15 to 20 tons of ore daily, this being handled by aerial-tramway.

Mogollon, June 19.

OREGON

JOSEPHINE COUNTY

(Special Correspondence.)—The Queen of Bronze mine continues to ship 500 tons of copper ore monthly, working 65 men. There is a large amount of ore in sight. Roy Clark is manager. —The Waldo copper mine is under lease to local parties. In an eight months' run last year, this mine yielded ore valued at \$65,000. De Witt Van Ostrand, of Phillips, Wisconsin, and A. H. Gunnell, of Grants Pass, are interested in this property.

The Maybell, Little, and Cow Boy mines are under lease to C. E. Tucker and George Fife, who are shipping high-grade ore to the Tacoma smelter.

The Lilly copper mine, which adjoins the Waldo on the south, is under option to M. A. Delano, of Grants Pass, who is shipping high-grade ore to the Tacoma smelter, by way of Grants Pass.

Takilma, June 14.

(Special Correspondence.)—D. R. Morrison shipped the first car of ore from his Pickett creek copper mine last week. It will average 10%. The shipment went to the Tacoma smelter.

Merlin, June 16.

(Special Correspondence.)—Another clean-up at the Simmons-Logan placer mine yielded \$7000 in gold and \$1000 in platinum in a run of 26 days. This property is owned by Mrs. Jane Simmons, of Grants Pass, and J. T. Logan, of Waldo, and has been a dependable producer for many years. It comprises about 1500 acres and is operated by hydraulic-elevators. Water is obtained from the branches of the Illinois river. There are 25 miles of ditches and pipe-line.

Waldo, June 15.

(Special Correspondence.)—A large body of chrome ore has been opened up near Oak Flat on the Illinois river. A motor-truck road 14 miles long is to be finished by July 1 to connect the mines with the county road at Selma. R. J. Rowan is manager.

A mining deal has just been closed on the Gray Back copper mine, which is situated 13 miles east of Selma and three miles from the Oregon caves. The property is taken by the Twohy people, represented locally by John Humpshire of Grants Pass. Development is to commence at once, and will include the building of a new road six miles long. There is 700 ft. of development work on the property, all adits. The property

was sold by W. L. Babcock, the owner, for the past 16 years, he having developed the group. The price has not been made public.

Selma, June 16.

(Special Correspondence.)—The Williams chrome property on Sexton mountain, consisting of 160 acres, has been leased to George S. Barton, of Grants Pass. Arrangements have been made for a large crew of men. This property was found by J. J. Williams, of Pacific Grove, California, a short time ago when surveying timber. There is 250 tons of ore in sight. It will be hauled to Threepines for shipment.

The United Copper company's mine on Grave creek is making regular shipments of high-grade concentrate to the Tacoma smelter. Some rich sulphide ore also is being shipped. Chromite mining is a comparatively new industry in northern California and southern Oregon. Until the War, no ore was shipped from this region. This season every ton that is available finds a ready market. Buyers have been scouring the district all winter and spring.

Grants Pass, June 17.

(Special Correspondence.)—On June 9 the Williams chrome property, on Sexton mountain, consisting of 160 acres, was leased to George S. Barton, of Grants Pass. Barton has arranged for miners and will begin work at once, mining and shipping ore. The property has been owned by J. J. Williams, of Pacific Grove, California. There is now over 250 tons of ore ready, which will be hauled to Threepines for shipment. The sale of this property is but one of several recently made. Already large investments have been made in buying and developing available properties, which show extensive bodies of ore, and the operators are assured of a profitable market. During the past year the first permanent development was done on the prospects in this district, when approximately 2000 tons of the ore was shipped to Chicago and Pennsylvania. Chromite occurs in many places in this county. Some of it was used at the copper furnace at Takilma, in this district, as a refractory-lining for which it was found to be well suited.

Those who have been searching this region for minerals are surprised at the richness of the placers in platinum.

John Hampshire, of Grants Pass, the local representative of the Twoby Bros. Company, owners of the railroad and smelter in the Waldo district is at Crescent City, California, investigating the company's properties in that district. All the men available are employed on the Low Divide, and other chrome properties which they have recently purchased. Shipments will soon commence. Their new purchases on Copper creek are opening up fine, and it appears there is a large amount of high-grade ore there.

Grants Pass, June 11.

(Special Correspondence.)—The Webb copper mine seven miles south-west from Waldo has been taken over by the interests now controlling the Greenback mine. The option agrees to transfer the mine from D. L. and L. R. Webb Bros. to D. R. Robinson. The property must be continuously and vigorously developed, and the ore mined is to be sorted and shipped.

The Webb property consists of nine claims, on which 1500 ft. of development has been done. The main adit 450 ft. long cuts the main vein 390 ft. in, where it is 22 ft. wide. Driving on the vein is under way. The deal settles litigation over the ownership, which has been in progress the past two years, and prevented proper development work.

A. M. Swarthly, account director of the Oregon Bureau of Mines and Geology, spent three days in the Waldo district in the interest of a series of experiments being conducted by the bureau in conjunction with the Federal Bureau of Mines, the object being to find a commercial practicable method whereby the pyrrhotite can be separated from the chalcopryite in the ore. A satisfactory solution of this problem would be of great value to the southern Oregon mines.

The Logan placer mine, situated near Kirby, shipped to the

mint last week five gold bricks, valued at \$7000, the clean-up from the run of 26 days. Along with the shipment was platinum to the value of \$1000, which was included in the clean-up. The experts who have recently visited in southern Oregon have found nothing that interested them more than the platinum found in almost all the placer deposits. There is little doubt that from the early days of placer mining in this region, a great deal of platinum went through the sluices.

Grants Pass, June 1.

SOUTH DAKOTA

LAWRENCE COUNTY

(Special Correspondence.)—The Trojan, Mogul, and Golden Reward mining companies, in the Bald Mountain district, have given their miners an increase of 50c. per day, for shift of eight hours. Wages now are: Miners, \$4, shovelers, \$3.50. The increase affects about 300 men about the mines.—Work underground at the Ora Honda has been discontinued, while awaiting the arrival of a new hoisting-engine.

Lead, June 16.

TEXAS

BRAZORIA COUNTY

(Special Correspondence.)—The first unit of a chemical-plant that will represent when completed a total investment of about \$450,000, has just been finished and placed in operation here by the Freeport Chemical company, a subsidiary of the Stauffer Chemical company, of San Francisco, California. The new industry is devoted to the manufacture of sulphuric acid and other chemical products.

In order to meet the increasing demand for sulphur and its products the output of the large sulphur mines here is being increased. It is stated that the United States used last year approximately 900,000 tons of sulphur as compared with 300,000 tons the year before the outbreak of the War. It is expected that the demand of this country will reach more than 1,000,000 tons during the present year and that it will increase to 1,600,000 tons within another year, if the present war continues. The sulphur deposits of Texas and Louisiana are almost the sole source of supply. The mines here are situated adjacent to the Brazos river and near the mouth of that stream. Deep-water channel of 18 ft. is available for vessels, but it is found that the smaller vessels are insufficient to meet the shipping demands and it is now proposed to deepen the channel to 25 ft. at an estimated cost of \$455,000.

Freeport, June 8.

LLANO COUNTY

(Special Correspondence.)—Considerable molybdenite is being shipped from here to Orilla, Ontario, Canada, where it is concentrated and shipped to England. The ore comes principally from the mine near here that is owned by N. J. Badu and associates, of Llano. More than 2000 tons have been shipped.

Llano, June 14.

WASHINGTON

FERRY COUNTY

(Special Correspondence.)—The Knob Hill Co. has finished grading and is sinking its new shaft, over which a head-frame is being built. At a depth of 100 ft. a cross-cut will be driven to the main vein 700 ft. below the cropping. This is 100 ft. deeper than the lowest workings. The gasoline-hoist, at present in use, will be replaced by more powerful machinery. After paying a dividend of \$10,000, a reserve of \$27,000 is left; 18 cars of ore are at the smelter, and several more cars are being loaded for shipment.—In the Lone Pine mine, the Day Brothers are sinking the main working-shaft by contract 250 ft. deeper, and will let a contract for driving 500 ft. on the vein. The ore is going to the smelters under contract at the rate of 100 tons daily.—E. J. Delbridge, lessee of the Tom Thumb mine, owned by the Midget Co., is employing five men in ex-

tending a 100-ft. adit to reach the Rebate vein, now owned by the Midget Co.—The Ben Hur mine has been leased to J. A. Wiseman and Thomas Gardiner.—The Belcher mine, in Belcher district, has sent 1600 tons of ore to the Granby smelter at Grand Forks, B. C., being a part of a contract for the delivery of 5000 tons. The smelter is closed down at present, on account of the coke-shortage.—J. E. Lancaster has shipped 50 tons of ore from the Boston and New York groups, near Curlew. The ore contains 10 to 12% lead and 5 to 8% copper, with 25 to 30 oz. silver per ton.

The Virginia Mining Co., operating near Danville, has installed a crude-oil engine and compressor on the Lucille Dreyfus mine, and is making regular shipments of gold and silver ore.

Republic, June 12.

CANADA

BRITISH COLUMBIA

The Hedley Gold Mining Co. (Nickel Plate mine) has declared a quarterly dividend of 3%, and an extra dividend of 2% on the outstanding capital stock of the company, payable June 30, to stockholders of record June 23.

NEW BRUNSWICK

The copper mines at Dorchester which were re-opened several months ago after 16 years of idleness, says the *Daily Metal Reporter*, have made the first shipment of concentrate, consisting of 30 tons, estimated to contain 30% copper and about 15 oz. silver to the ton. Fortnightly shipments are expected hereafter. The company is an American concern, with offices in Boston. The method of mining the ore is by chamber work. The copper is found in veins with a 20° pitch. At present the exposed face of ore is 12 ft. high and from 200 to 300 ft. long.

MEXICO

SONORA

(Special Correspondence.)—The only mine working in the Alamos district, in Sonora, at the present time is La Cacharamba, eight miles west of the city of Alamos, in the famous Quintero-Promontorio silver belt. This mine belongs to the Plata-fina Mining & Development Co., of which E. G. Swayze is president, and T. B. Brinegar general manager. Mr. Swayze affirms that development work during the revolution has put into sight 15,000 tons of ore in this mine, having an average assay value of \$30 in silver. The same company is developing two new mines, and has in all six ore-shoots opened up. The branch of the Southern Pacific railroad from Navajoa to Alamos has been abandoned for several years, and shipping is carried on by wagons from depots established at Navajoa. There are rumors that an American syndicate has taken an option upon the Quintero, but we understand that this is denied by the house of Robinson Bours. The Tónichi branch of the Southern Pacific has also been abandoned for a long period, and will require the expenditure of a great deal of money to put it into working order. All mining operations along the line of that road are dead, but the manager of the La Dura mines recently outfitted at Alamos and went across country to La Dura to look over the ground, with a view to resumption of development work. The Anita mines, belonging to the Pacific Smelting & Mining Co., a New York corporation, are also closed. For a time they were shipping high-grade copper ore to the El Paso smelter. Exchange at Alamos is now on the basis of ₧1.70 for \$1, but at Nogales, on the border, exchange has reverted to the pre-revolutionary rate of ₧2 for \$1. Mining development in Sonora is at a standstill.

Alamos, June 14.

KOREA

The Seoul Mining Co., operating the Suan concession, in Whang Hal province, reports for the month of May a total recovery of \$153,527.

Personal

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

HENRY HANSON has gone to Peru.

GEORGE O. SCARFE is at Le Pas, Manitoba.

CHARLES JANIN has returned from Russia.

CHARLES R. FETKE is examining oil-lands in Kentucky.

KENNETH J. HLEBNIKOFF is returning to Harbin, in Manchuria.

H. VINCENT WALLACE expects to go shortly to Guanajuato, Mexico.

H. ABEY is returning to Japan on the 'Tenyo Maru,' sailing on June 30.

MARK R. LAMB is now occupied in the export business at New York.

M. W. VON BERNEWITZ is examining ancient gravel channels near La Port, California.

F. H. MINARD passed through San Francisco on his way from New York to Medford, Oregon.

W. M. BREWER has been appointed resident engineer for the Western district of British Columbia.

C. GORE-LANGTON is engineer for the Great Western Electro-Chemical Co., at Pittsburg, California.

ROBERT H. CHAPMAN has left Washington to perform military duties at Tobyhanna, Pennsylvania.

S. C. DICKINSON has been appointed safety engineer for the Arizona State Bureau of Mines at Tucson.

W. B. BLYTH and F. A. MARRIOTT have entered into an engineering partnership in Bulawayo, Rhodesia.

E. MICHOT and X. PICHON, of the Boleo Copper Co., passed through San Francisco on their way to New York.

FRANK C. LAURIE has been appointed superintendent for the Freeport & Tampico Oil Corporation, at Tampico, Mexico.

V. F. MARSTERS and CHAS. N. GOULD have opened a consulting geological engineering office at 316 Rialto building, Kansas City, Missouri.

F. O. JASMER has just returned from an extended trip through the central and western part of Mexico, and is leaving for New York about July 1.

CHARLES E. PRIOR has resigned his position as chief engineer with the La Blanca mine, at Pachuca, Mexico, in order to volunteer for military service.

W. S. NOYES, who has been the victim of legal persecution for three years, was acquitted on June 20, the judge instructing the jury to bring in a verdict of not guilty, holding that no case had been made.

The Walter A. Zelnicker Supply Co., of St. Louis, announces the appointment of KARL W. BOCK as manager. Mr. Bock was, for the last ten years, secretary of and assistant to the vice-president of the Union Pacific Coal Co. and subsidiary coal companies at Omaha.

E. F. BURCHARD has been appointed chief of the new section of the United States Geological Survey to cover geologic investigations of the ores from which are derived the alloy metals used in making special steels. G. F. LOUGHLIN will assist Mr. Burchard in the non-metallic section of the division of mineral resources.

The address by ROBERT C. STICHT before the San Francisco section of the A. I. M. E. will be delivered on July 17, not July 10, as first announced. The meeting will be at the Engineers Club at 8 p.m., preceded by the usual dinner at 6:30. The subject is 'Pyrite Smelting,' a branch of metallurgy in which Mr. Sticht has so greatly distinguished himself.

VICTOR VIDERTON, a mining engineer, of Globe, Arizona, died at San Francisco, June 25, at the age of 60 years.

Eastern Metal Market

New York, June 20.

Nearly every metal in the metal-market still hangs fire awaiting the action of the Government. This is getting to be an old story and is wearing on the nerves of many who are interested in this branch of trade.

Copper continues firm but more or less dull.

Lead is quiet and a little easier.

Tin is dull but higher on the uncertainty of the London market, due to absence of cables.

Antimony is again lower with demand very light.

Interest in the steel market centres in the continued advance in steel prices with no signs of control. Many producers have ceased selling despite high offers from eager and anxious consumers, while others have refused to advance prices, as in the case of the leading wire interests, but the intended effect has not resulted. The world-wide famine in plates which has sent prices up twice as far as those of other steel-products sold in the same level, coupled with the need of the Government for more plates for ship-building than for anything else, has mixed up the price-fixing problem. Manufacturing consumers are trying harder than ever to get protection on finished steel for 1918, but with little success so far. The pig-iron market is quieter.

COPPER

The market continues a waiting one—the same old story—waiting for some action by the Government and its Allies regarding the quantity and the price of the copper to be needed. No definite trend in the market, up or down, is expected, until this matter is settled. Conditions remain practically unchanged. If anything, the market is a little easier, but it is still firm and strong. Sales of small volume are being continuously made for all positions but there is no large demand. Metal desired this side of August is obtainable only from small producers or second hands with early delivery quoted about nominal at 32.50c., New York. The quotation for third quarter, outside of July, is 30.50 to 31c., New York, with fourth quarter at 29 to 29.50. July metal is generally pegged at 31.50 to 32c. It is persistently rumored and confirmed in some quarters that the Government is now having copper delivered for its use at 28c. per lb., though it is stated that this is not a definite settling price but merely one selected for billing purposes, the real price to be paid to be decided upon later. Absence of exact information is a very unsettling factor. The status of the London market is not known in the absence of cables so far this week. At last advices prices were unchanged there from those quoted a week ago in this report.

TIN

It is unusual for cables to the New York Metal Exchange to be lacking for two days, but so far this week none have come from London. This has caused considerable unsettlement and confusion in the trade. No satisfactory explanation is offered. Private advices by cable to a couple of firms reveal a decided advance in the London tin market, exceeding £8 per ton. As a result of this, prices were marked up on Monday and Tuesday here nearly 3c. per lb. above those at the end of the previous week. Yesterday the more or less nominal price was 63.50c., New York, with the price for Monday at 64c. On Wednesday, Thursday, and Friday last week the quotations, based on sales, were 60.75c., 61.25c., and 61.75c., New York. The absence of cables has caused a temporary halt in the market with sellers restless and buyers shy and with naturally a disinclination to commitments on either side. A fair volume of business was done last week in a quiet way in future shipments from the East. On June 13 August shipment from the East sold at

54.75c., with September at 54.62½c. On the 14th August and September shipment went at 55.66½c., and on the 15th, September shipment commanded 56.25c. On June 14 there were fair sales of spot tin at 61.25c., New York. Tin arrivals up to and including June 19 were 1095 tons, with the quantity afloat at 3156 tons. Banca tin is about 3c. under the regular prices.

LEAD

It is confidently believed that some definite understanding has been reached between the Government and the lead interests as a result of the meetings last week. While the actual quantity to be needed is understood to be still in abeyance, the price agreed upon, while not officially announced, is stated to be 8c. per lb. or about 4c. under the present market and about double normal prices. It is also generally reported that the quantity to be needed does not come up to the expectations of many up to this time. That these reports are more or less true is partly borne out by the fact that large producers who have been consistently refusing to sell so as to take care of large Government needs, are now offering some metal and by the fact that the price is declining. Yesterday the New York quotation was 11.75c. with 11.50c. as the St. Louis figure. The entire market is very much quieter than for some time and there has been a considerable falling off in sales. It is difficult to forecast the future, but continued high prices are looked for by many. The American Smelting & Refining Co. still quotes 11c., New York.

ZINC

With demand at a standstill and with large dealers or producers firm in their position, quotations continue more or less nominal. Prompt June metal may be regarded as a little easier perhaps at 9.67c., New York, but futures continue firm at 9.75c., New York, or 9.50c., St. Louis. The ore market continues its sustaining influence, for while ores are high, the metal itself cannot be expected to recede much. The belief persists also that business inside of a few weeks will take on more activity, and this sentiment tends to strengthen the market. Until something definite is known as to the Government's requirements, continued inactivity is expected.

ANTIMONY

In the absence of active demand the quotation for nearby metal continues to recede and Chinese and Japanese grades are quoted at 19 to 20c., New York, duty paid. There is more interest in futures and some good sales are reported.

ALUMINUM

The president of the Aluminum Company of America, Arthur V. Davis, announces that his company has offered to meet the Government's requirements for aluminum at 27.50c. per lb., this figure having been arrived at by adding 2c. per lb. to the average for the last 10 years. No. 1 virgin metal, 98 to 99% pure, is quoted at 59 to 61c., New York, with demand of small proportions.

ORES

TUNGSTEN: Quotations are unchanged at \$20 to \$22 per unit for 60% concentrates, but it is reported that the demand is greater than the supply. Canada is again in the market. Ferro-tungsten is quoted at \$2.25 to \$2.50 per lb. of contained tungsten.

ANTIMONY: There is no change in the quotation which continues firm at \$2.30 per unit.

MOLYBDENUM: Not much ore is being offered and prices remain firm at the unchanged quotation of \$2.10 to \$2.20 per lb. of MoS₂.

THE METAL MARKET

METAL PRICES

San Francisco, June 26

Antimony, cents per pound	19.50—22.00
Electrolytic copper, cents per pound	34.50
Pig lead, cents per pound	12.25—12.50
Platinum, soft and hard metal, per ounce	\$105—111
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	11.50
Tin, cents per pound	59
Zinc-dust, cents per pound	20

ORE PRICES

San Francisco, June 26

Aluminum-dust (100-lb. lots), per lb.	\$1.00
Aluminum-dust (ton lots), per lb.	\$0.95
Antimony, 50% metal, per unit	\$1.45
Chrome, 40% and over, f.o.b. cars California, cents per unit	50—55
Magnetite, crude, per ton	\$8.00—12.00
Tin, cents per pound	60
Tungsten, 60% WO ₃ , per unit	20.00
Molybdenite, per unit for MoS ₂ contained	40.00
Manganese, 45% (under 35% metal not desired), cents, unit	36—38

Manganese prices and specifications, as per the quotations of the Carnegie Steel Co. schedule of prices per ton of 2240 lb. for domestic manganese ore delivered, freight prepaid, at Pittsburg, Pa., or Chicago, Ill. For ore containing

Above 40% metallic manganese	Per unit \$1.00
46 to 49% metallic manganese	0.98
43 to 46% metallic manganese	0.95
40 to 43% metallic manganese	0.90

Prices are based on ore containing not more than 8% silica nor more than 0.2% phosphorus, and are subject to deductions as follows: (1) for each 1% in excess of 8% silica, a deduction of 15c. per ton, fractions in proportion; (2) for each 0.02% in excess of 0.2% phosphorus, a deduction of 2c. per unit of manganese per ton, fractions in proportion; (3) ore containing less than 40% manganese, or more than 12% silica, or 0.225% phosphorus, subject to acceptance or refusal at buyer's option; settlements based on analysis of sample dried at 212° F., the percentage of moisture in the sample as taken to be deducted from the weight. Prices are subject to change without notice unless specially agreed upon.

EASTERN METAL MARKET

(By wire from New York)

June 26.—Copper is inactive and nominal at 32.50 to 32.25c. Lead remains quiet at 11.75c. Zinc is dull and easier at 9.50 to 9.37c. Platinum remains unchanged at \$105 for soft and \$111 for hard.

The quantity of platinum in the United States is estimated by the United States Geological Survey at 1,000,000 troy ounces, besides which there is over 400,000 oz. of other metals of the platinum group, principally palladium, iridium, and rhodium. In 1916 the crude platinum mined in Colombia (25,000 oz.) was refined in the United States, and 28,088 oz. of metals of the platinum group was recovered by American refiners from all sources, foreign and domestic, of which 24,518 oz. was platinum.

It is estimated that 30,000 oz. of crude platinum, containing 85% metal, will be produced in Colombia in 1917, and that the production of Russia and the United States will be considerably increased.

According to the manager's report at the recent annual meeting of the Hongkong & Shanghai Banking Corporation, it is the coinage demands of the belligerent countries, including the expenditure on military operations in Egypt, East Africa, and Mesopotamia, that have been a contributing cause to the remarkable rise in the price of silver. "But the rise was chiefly due to the purchases made by the Indian government, who bought during the course of the past 12 months some £15,000,000 worth of silver. The balances in the Indian currency reserves were reduced by 16 crores be-

tween August 1915 and March 1916, and had to be replenished by large purchases of the metal, the urgency of which has been in no way diminished by the heavy withdrawal of rupees which is still going on.

"These demands of the Allied governments for coinage, and of the Indian government to replace the enormous absorption of silver rupees by the natives of India, where gold was not available for hoarding purposes, have more than kept pace with supplies. Outside sources of supply were tapped; the equivalent of 8,350,000 standard ounces was obtained from the Government of the Philippines in the form of peso coins, and the movement of silver funds into gold securities necessitated a heavy export of silver from China. There is no escape from the conclusion that the amount of silver left in China must be barely sufficient for trade requirements, and assuming, as we have every reason to, that there will continue to be a strong demand for the products of China, it would appear inevitable that China must again be a competitor in the silver market."

The tin market is still upset, due to the non-receipt of cables from London. A slight advance is expected in London, but the present home market is quoted nominally at 63c. with Banca and Chinese tin at a marked discount.

TUNGSTEN

There is still more demand than supplies, and on top of the home demand, Canada has again come into the market, especially for scheelite. The market is quoted \$20 to \$22 for high-grade material.

MOLYBDENUM

Molybdenum remains unchanged and firm with prices varying from \$2.10 to \$2.20 per pound MoS₂ with very little material offered.

ANTIMONY

Antimony has been active during the past week and prices for spot range from 19½ to 19¾c. Needle antimony is still firm at 12c for spot, with futures quoted at 9½c. Antimony ore remains firm at \$2.30 per unit.

MANGANESE

The demand for manganese continues and \$1 per unit has been paid for high-grade furnace ore during the last week f.o.b. New York. Chemical ore prices are practically the same.

Book Reviews

STRESSES IN STRUCTURAL STEEL ANGLES, with Special Tables. By L. A. Waterbury, C.E. Pp. 77. John Wiley & Sons, Inc., New York, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.25.

The text in this handy little volume is limited to 27 pages; it is intended merely to present the fundamentals of theory for ready reference in the use of the tables which the author has calculated, and which constitute the great value of the work for the engineer. These tables present the data for all conventional structural sizes of steel shapes in common use, relating to the following: elements of angles with equal legs; elements of angles with unequal legs; co-ordinate of section modulus polygons for angles; efficiency and allowable tension for angles riveted through one leg to a rigid connection-plate, when two holes for $\frac{3}{8}$ in. rivets are deducted from the connected leg; and efficiency and allowable tension for angles riveted through one leg to a rigid connection-plate, when one hole for $\frac{3}{8}$ in. rivet is deducted from the connected leg. The author presents the development of formulæ for the relation between bending-moment and flexural stress; section modulus; product of inertia; section modulus polygons; neutral axis; plane of loading; combined stresses; flexure for angles in pairs; transfer of stress by shear to an outstanding leg; and efficiency of end-connections. The latter is discussed in relation to a large number of values of efficiency, of equivalent effective area, and of total permissible tension, for a maximum unit-stress of 16,000 lb. per sq. in., computed in accord with the method developed in the text. The book is characterized by a practical, clean-cut discussion, and by a systematic, well-arranged set of tables, all which should commend it as a valuable office-assistant to the designer of steel structures.

STEAM TURBINES. By James Ambrose Moyer. Third Edition. Pp. 460 and index. Ill. John Wiley & Sons, New York and London. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$3.50.

This excellent work is a compendium for power users, being a practical and theoretical treatise for engineers and students. It reviews completely the recent improvements in the economy of steam-turbines, and as the author says, "The low cost of power where fuel is cheap makes the large turbine-electric generating-plant almost an unrivaled competitor of water-power for metallurgical purposes. Many changes have been made in some departments of the book and it is in every sense up-to-date. All who contemplate large power installations should secure this book in order to be fully informed in the most modern practice in the generation of power for any purpose whatsoever. In an appendix is a series of questions for the student who soon may have these very questions presented to him in actual practice.

OXY-ACETYLENE WELDING PRACTICE. A Practical Presentation of the Modern Processes of Welding, Cutting, and Lead-Burning, with Special Attention to Welding-Technique for Steel, Cast-Iron, Aluminum, Copper, and Brass. By Robert J. Kehl, M.E., Ill.; index; pp. 102. American Technical Society, Chicago, 1917. For sale by MINING AND SCIENTIFIC PRESS. Price, \$1.

The author states succinctly that the advantages of the oxy-acetylene over the oxy-hydrogen process for welding consists in the easy control of the heat developed by the flame, which is approximately 6300° F. and in the abundant supplies of carbide and dissolved acetylene that are available in every industrial centre in the United States, as well as in the cheap-

ness of the apparatus required and the low cost of operation. No automobile repair-shop today can dispense with this handy equipment, and no mine or metallurgical works of any size should be without it. The more remote from the railroad or the city the greater is the need of it ready at hand to meet every emergency. The acetylene generator and the cylinder of oxygen cost little compared with delays, and with the annoyances of imperfect repair-work attempted with the forge and other devices. This little treatise tells the whole story of the use of the equipment and the range of applicability. The author describes with the aid of a multitude of photographs and diagrams the entire technique, so that it becomes a guide-book from which one might teach himself the art. It is a manual of procedure that should be welcome in every shop. He also explains blow-pipe cutting of metals with oxygen, and lead-burning, not the sort that is required for lining vats with sheet-lead nor for autogenous welding of large sheets as practised in the construction of sulphuric-acid chambers, but the small jobs that come up in automobile repairing, and in fixing lead-pipe and other connections where acids are handled in a metallurgical works. The discussion of oxy-acetylene welding of copper, brass, and bronze, will also be appreciated.

PRELIMINARY MATHEMATICS. By Prof. F. E. Austin. Pp. 169; index. Published by the author, Hanover, N. H., 1917. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$1.25.

Professor Austin has a knack for stripping off the non-essential and non-elucidative in writing text-books. In this tiny volume is compressed a full course in algebra required for entrance examinations to any first-class college. Like his 'Examples in Magnetism,' and his little books on 'High Pressure and Low-Pressure Transformers,' this little algebra covers the field as to its essentials, and in a form of statement that is lucid, even if at times he commits the mathematician's common error of leaping a fence and leaving the student struggling to see how he got over it. Sometimes, we think he employs a mathematician's statement of a problem, clear and correct enough but not in the order of thought natural to the untrained mind. It is a question of opinion, but we think that a child, undertaking to ascertain when the ages of father and son, now respectively 33 and 12, stood in the ratio of 4 to 1, would not have stated his problem in the terms $33 - X = 4(12 - X)$; we believe the child-mind would have used the 4 as a divisor of the first term of the equation. As a self-teacher we believe the book to be a trifle too economical of explanation, but as a base to teach from we recommend it as peculiarly satisfactory.

HANDBOOK OF CHEMISTRY AND PHYSICS: A Ready-Reference Pocket Book of Chemical and Physical Data. 5th Ed. Pp. 410; index. The Chemical Rubber Co., Cleveland, Ohio, 1917. For sale by the MINING AND SCIENTIFIC PRESS. Price, \$2.

This *vade mecum*, truly of pocket-size, and packed with data of chemical and physical constants, has been brought up to date by compilation from accepted first-hand sources of information. One of the most useful tabulations in the book relates to the physical constants of the elements, and of inorganic and organic compounds. As an illustration of the scope of the tables we may note that, for the inorganic compounds, the table gives the name, formula, molecular weight, crystalline form and color, specific gravity, melting point, boiling point, and solubilities in water (cold and hot) and in alcohol, acids, and alkalis. There is also a table of gravimetric factors and logarithms, one on heats of formation for chlorides, oxides and hydroxides, and sulphides; various acid and alkali tables, specific heats of elements and various solids; heat equivalents of vaporization; vapor tensions; and hundreds of others. No single handbook will answer every question, but this will answer so large a number as to save many a long hunt through voluminous textbooks.

Company Reports

UTAH METAL & TUNNEL COMPANY

The second annual report of the Utah Metal & Tunnel Company shows the following:

Gross value of ore mined.....	\$1,499,267.69
Income from rents, water, etc.....	35,946.62
	<hr/>
	\$1,535,214.31
Expenses:	
Smelting and refining charges.....	\$377,304.58
Mining	247,907.36
Development	148,713.08
Hauling	7,251.36
Lease ore	26,411.07
Milling	67,528.31
Selling, administration, and general expense..	58,267.94
	<hr/>
	\$933,383.70
Operating profit	601,830.61
Interest and discount earned.....	18,102.65
	<hr/>
	\$619,933.26
Taxes	19,851.90
Interest on bonds	15,245.88
	<hr/>
	\$35,097.48
Net profit less depletion.....	584,835.48
Depletion charge	56,098.16
	<hr/>
Profit	\$528,737.32

THE CANADA COPPER CORPORATION (LTD.)

The annual report of the Canada Copper Corporation, Limited, for the year ended December 31, 1916, contains the following:

From the Greenwood, B. C., property a net profit of \$215,304.85 was made after deducting depreciation to the amount of \$235,238.37.

The total ore smelted during the year was 306,450 dry tons, of which 23,243 tons was custom ore. This ore produced 5,196,239 lb. of copper, 49,928.71 oz. silver, and 12,366.24 oz. gold.

The Mother Lode mine supplied 256,784 tons of ore, averaging 0.945% copper, 0.034 oz. gold, 0.160 oz. silver. It was only possible to operate the smelter because of the high price of copper. High cost of operating was due to the ore being taken from pillars and caved areas remaining in the mine, and to the high cost of labor and supplies. Smelting operations were much interfered with, due to a continuous shortage of coke.

The Copper Mountain property was provided with a power-transmission line 13.6 miles long, and compressor, machine, blacksmith, and carpenter-shops were provided. Also warehouses, bunk-houses and additional dwellings, as well as other necessary improvements. A 50-ton flotation-mill was built and operated throughout the year.

An adit 9 by 9 ft. was driven 2100 ft. The total of driving, raising and lateral drifts being 5200 ft. Over 8000 ft. of diamond-drilling was done, and 2364 ft. of surface trenching was performed. During the year \$396,000 was expended in the equipment and development of this property.

It is estimated that the ore reserves of the Copper Mountain contain 10,000,000 tons definitely assured and 2,000,000 tons of probable ore. The average grade of this tonnage is 1.74% copper and 20c. per ton of recoverable gold and silver.

The company holds a large area of property that is only partly developed; that on Kennedy Mountain having been superficially prospected by means of 1777 ft. of diamond-drilling and 956 ft. of adits.

The company is negotiating with the railroad company for the early construction of a branch from Princeton to Copper Mountain, 13 miles. Arrangements are also being made for additional power, and for the disposal of the concentrate produced in the mill.

Mining Decisions

MINING OPTION—OPTIONEE NOT BOUND

Entrance on the property for the purpose of prospecting the same by the holder of an option covering mining ground does not constitute a taking up of the option to which the optionee could be held, even though the option provided for an "acceptance" by the optionee prior to making payments.

Johnson v. Clark (California), 163 Pacific 1004. March 13, 1917.

COAL LEASE—MINIMUM ROYALTIES

Under a mining lease providing for minimum royalties, the lessor may recover the same whether any coal was mined or not, upon failure of the lessee to surrender the lease before the royalties became payable.

Saylor Park Land Co. v. Glenwood Coal Co. (Iowa), 162 Northwestern, 203. April 5, 1917.

MINERS LIENS—BORROWED MACHINERY SUBJECT TO

Partners lending donkey engines to a mining company which were subsequently used by miners employed by that company with the full knowledge and acquiescence of the partners, are estopped from defending against mechanics liens placed thereon by the miners.

Rogers v. Reynolds (Washington), 164 Pacific, 80. April 3, 1917.

ABANDONED OIL LEASE—REMOVAL OF MACHINERY

Eight months is a reasonable time within which an oil lessee may remove pipe left in the ground upon abandoning his lease, where the lease gave the lessee the right to remove all machinery, fixtures, and improvements at any time.

Standard Oil Company of Louisiana v. Barlow et al. (Louisiana), 74 Southern, 627. March 12, 1917.

MARKING BOUNDARIES—ATTITUDE OF COURTS

Acquiring certain antimony mining locations in 1906, 1907, and 1908, appellant thereafter expended some \$25,000 in developing the property, installing mining equipment, digging water ditches, constructing roads, tunnels, cross-cuts, and other workings, and doing the annual assessment work each year until 1914. In April 1915, respondent, who had assisted in performing the assessment work on the claims in 1913 and was thoroughly familiar with their boundaries and extent, went on the ground and located it as vacant and unoccupied government land. Held, that no title was acquired by respondent. Being familiar with the boundaries and extent of the claims, he cannot be heard to claim an insufficient marking of boundaries, and having located it as "vacant and unoccupied government land," he cannot base his title on a re-location of forfeited ground. The courts express a liberal policy in the matter of adjudging compliance with the statutes requiring marking of boundaries by those who have spent time and money in good faith in the development of mineral ground.

Gold Creek Antimony Mines & Smelting Co. v. Perry (Washington), 162 Pacific, 996. February 13, 1917.

two upper gears are mounted on a carriage by means of which they are swung through a certain angle by the thrust-cylinder.

At the bottom of the cylinder is a self-draining valve (a) operated by the rod (b), which also operates the oil by-pass or cataract-valve (c). The rod (b) is connected by a rod (d) to a floating-lever (e), whose other end is supported by a rod (f), which is attached to the mechanism moved by the thrust-cylinder, in this case the reverse-carriage.

When the operating lever is shifted to the right the floating-lever (e) is lifted about (g), as a fulcrum, since rod (f) is held stationary. Rod (b) rises, opening the steam-valve (a) and the oil-cataract valve (c). The steam-piston rises and simultaneously lifts the lever (f) and the pin (g). The floating-lever now moves about point (h), as a fulcrum, so that rod (b) moves downward to close the steam-valve (a) and cataract-valve (c). Steam is shut off and the closure of the oil-valve locks the piston in the oil-cylinder. The cross-head has been moved and locked in a position corresponding to the movement of the operating-lever. In other words, the entire mechanism

only is necessary to have the brake clear equally all around.

This design of brake in connection with the thrust-cylinders with floating-lever control, gives the operator full control of the braking, exactly as though the brakes were operated by hand. He can regulate the speed with which the brakes are applied, or released, and control the brake-pressure with the utmost delicacy.

All thrust-cylinders should be of long stroke so as to get flexible and accurate control. The cataract-cylinder should also be provided with a valve, and not merely a by-pass port, into which a plug is screwed to restrict the passage of oil from

FIG. 3

has followed the movement of the operator's lever and, as soon as he ceases movement, the mechanism has the same control over it as though it were directly operated by hand. Brakes, clutches, reversing-gear and throttles, where necessary, are operated by this device.

AIR OPERATED:—Fig. 2 shows the arrangement of a thrust-cylinder operated with air. In this case the mechanism is shown for operating the gravity post-brake and the floating-lever control allows the operator to apply the brakes with full control of the speed of application and brake pressure.

In the drawing, the ends of the carriers A, B, C, D, form the corners of a parallelogram, such that the brake-post must move in a position parallel to itself. There are two sets of lever and draw-bars for drawing the brakes together, one at the top and one at the bottom, with provision for adjustment.

With this construction the brake-shoes have exactly the same pressure all around, so that there is no uneven wear in pinching which is present in all designs where the brake-posts are hinged at the bottom, or with band-brakes. A small movement

FIG. 4

one end of the cataract-cylinder to the other. This mechanism has the disadvantages of: (a), limiting the speed of operation, and (b), not serving as a positive lock for the mechanism.

HYDRAULIC OR OIL-OPERATED:—Fig. 3 shows the oil-operated thrust-cylinder at the left, also arranged to operate a gravity-brake. It consists essentially of the same floating-lever control, one end of the floating-lever operating the valves and the other end being attached to the mechanism that is moved, the operator's lever taking hold between these two points. The valve mechanism consists of two valves; one for admitting and the other for discharging the oil and the design is such that it is impossible for both the inlet and discharge-valves to be opened simultaneously. As soon as the motion of the operating-lever is stopped, the floating-lever closes both oil-valves and the piston is positively locked in any position desired by the operator.

For operating clutches, these thrust-cylinders are made double-acting by using two single-acting oil-cylinders, as shown in Fig. 3, and also in connection with the clutch-operating

rocker-arm and shaft in Fig. 4, which shows the electric-hoist at the Elm Orlu mine.

In conjunction with the hydraulic-thrust engines a small motor-driven pump in duplicate, and a pressure-accumulator

A New Publication

Water works pumping-plants have recently undergone a rapid and radical evolution.

The tremendously heavy and expensive, although efficient, triple-expansion pumping-engine has given place to the more compact, simple and less costly steam-turbine-driven centrifugal pump. The efficiency of the latter has risen steadily with the experience of its builders and with improvements in auxiliary equipment, until duties under standard steam conditions exceeding 150,000,000 ft.-lb. per 1000 lb. of steam are now obtained. The De Laval Steam Turbine Co., of Trenton, New Jersey, builder of the largest pumps of this type, has just issued, under the title 'progress in Water Works Pumps,' a 48-page booklet discussing the general, economic, and engineering conditions affecting the design and installation of such pumps. Installations in 15 of the principal cities of this country and Canada are described, including 34 units aggregating 999,000,000 gal. per day capacity. The publication should be of value to any one interested in the handling of water.

Fig. 5

are installed in a unit, as shown in Fig. 5. This makes the hoist independent of the mine air-supply and dependent entirely on the electrical power. Hydraulic thrust-cylinders are particularly well suited to the application of safety devices to prevent overspeeding and to insure slowing down as the dump is reached, and of reversal before starting.

The Oxy-Acetylene Method of Cutting Metals

For cutting off rivet-heads and stay-bolts flush with plates, by the oxy-acetylene process, it is desirable to have a cutting-tip so designed as to permit of the gas-jet playing parallel with the plates. To meet this need The Prest-O-Lite Co., Inc., of Indianapolis, Indiana, is manufacturing a special Rivet and Stay-bolt Cutting Attachment. This attachment is used in connection with the Type K Cutting Blow-pipe shown, being screwed into the head in place of the regular cutting-nozzles. The copper-tip is bent at a convenient angle and is adjustable to any position, facilitating operation in close quarters. Much cleaner work in rivet and stay-bolt cutting is possible with this attachment than with standard cutting-tips which do not permit of a cut that is truly parallel with the plates.

The Prest-O-Lite Co. has issued a new catalogue descriptive of the apparatus and methods of welding and cutting metals by means of the application of the oxy-acetylene flame. This outfit is of great service and value to mine equipment, and particularly to mines situated at a distance from towns where foundries and machine-shops are always available. The catalogue will be sent on application to the Prest-O-Lite Co. at Indianapolis, Indiana.

The Janney Flotation-Test Machine

The Stimpson Equipment Co. of Salt Lake City has issued a pamphlet descriptive of the Janney flotation-test machine which cannot fail to interest every flotation-operator in the country. The book is fully illustrated with half-tones and line drawings which scarcely require explanation. All who want to test the amenability of their ores to flotation should send for this latest contribution to the literature on flotation.

G. E. LAND has been appointed advertising manager for the Blaw Steel Construction Co. at Pittsburg, Pennsylvania.

RIVET-CUTTING ATTACHMENT

THE PREST-O-LITE CUTTING BLOW-PIPE
